Sage advice.

The mount strap for the fuel tank is mounted directly to the truck frame, so grounding isn't really going to be that big of an issue. I have the cab and the sleeper strapped together with 3" strap, the doors strapped to the cab with 1 1/2" strap, and the sleeper strapped to the frame with 3" strap. All the "strap" is tinned copper flat braid.

I know ground losses will be greater, but having the antenna longer will hopefully more than overcome that..

I could, also, tilt it back along the sleeper, but that gets it too close to the sheet metal, and I'll get coupling losses from that.

I've also changed my mind on using a SS whip on the top. 1" copper pipe would be better, and easier to guy/stabilize. I can fashion standoffs from the cab/sleeper junction out of PVC, too, if necessary.

This is going to be fun.. Maybe I should set up a switched cap/inductor at the feed point so I can force the antenna on to other nearby frequencies. A wheatstone bridge could take care of the controls...

Thanks for all the pointers.

1586. Re: How about a wire 1/4 vertical near a tree ???

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-28 19:54:35 UTC
From: Jim Leder <k8cxm@spam.fuse.net>
Message-ID: <SLwKd.7$VC6.2@fe37.usenetserver.com>
Source record: 82824

Every winter after the yard has been mowed for the final time and the leaves have been collected, I've been hanging a 1/4 wave wire from a tree branch. This year I have a 'dual' wire, one element for 30 and one for 20. I pound in a ground rode to hold it in place and they lay 16 radials 16 feet long around it on the ground with the ends held in with nails. The radials are connected to the ground rod. It works OK, not great, but OK. I also use a simple dipole up 40 feet on 30 and find the vertical works better under certain conditions, and it doesn't have the end nulls the dipole has. It's a nice temporary antenna and when snow is on the ground over those radials, it does work much better. When spring comes, I take it down and roll the radial wires up till next winter.
The wire vertical is maybe 15 feet away from the nearest tree, out on a limb, so to speak. The tree has never been a factor. 3 years ago I did the same thing for 40 and 30 and the wires were less than 6 feet from the tree and it seemed to work OK.

: That IS a dancing term. The question is in what proportion is it to
: antennas?

oh... set dancing is very much related to antennas.

you can have a set of 4, 6, 8 or more
all or some dancing together (driven in phase)
or all dancing to a slighly different pattern (out of phase)

some dancers were BOOTS...others dance BAREFOOT (10-4)

the proportion is as you like it, just depends how distant your
observation is....and of course how lacking one's understanding of
set theory is.

Thanks for all the pointers.

I've since found "vertload" as well.. I think I'm going to go that route. I can make something that will work for my purposes, and that's the point of all of this.

Thanks for all these great programs. If the "real world" works as predicted, then I should have something set up for next winter.

Back about 10 years ago, I built an antenna for my CB base (I wasn't a HAM then), and I was shooting blind. The SWR was, at best, 1.7:1, but boy did it get out. On the roof of the apartment, (2 stories tall) 3 blocks from the ocean in Oceanside, CA, I was able to hit Escondido on a legal 4 watts AM, 12 watts SSB, with an S7 or better... That's when I decided I liked working with building things. I've built every base antenna for both CB and HAM radio since then... Mobiles seem to act differently, and everything I've tried for mobile before now has come with mixed results. These programs you wrote for us will definitely be a big help.

Thanks again.. I'm gonna play with these and see what I can come up with for high efficiency, decent bandwidth (10-15KC would be enough!), for the sizes I have to deal with. Then, when I build it, I'll play with getting it to behave as designed.

Jack:

We're talking about a Semi tractor here.. It's already 13'4" tall, and in order to get this antenna where it would do the most good, it would have to be on one side or the other of the truck. Mounting it on the front bumper would make me over length, and make it impossible to open the hood for maintenance. Putting it behind the sleeper would raise it another 3 feet, and allow it to couple to the exhaust stacks, not to mention the back of the sleeper and the bulkhead on the trailer, and would kill the signal even more, not to mention the risk of having the trailer hit the antenna during turns, etc...

A whip will also blow around and change the SWR depending on how close/far it got to/from the metal sides of the sleeper.

I think a copper pipe will do better, and be easier to guy and keep out of the way.

Thanks

Most people have added an amplifier only to find out that the
difference in signal
was very small. Thus many people deride the value of a 'silly' db gain
whereas DX'ers say that a single db extra is a lot !
Fact is that most long distance signals on 20 metres come in at angles
of 11 degrees or less where as the 'normal' antenna has a TOA of around
14 degrees.
So where a dxer points to the extra 1db gain as being everything in
fact it is the lowering of the TOA that comes with the extra gain. In
my opinion if one designs his antenna for a lower TOA say 10 to 11
degrees then even tho its gain may well be below the dxers choise(a
very long boom or stacked antennas) the lower TOA with less gain will
show little difference
to the antenna of choics because the lower edge of the radiation lobe
will follow the same line and any extra gain provided will have the
same effect of adding an amplifier which is minimal compared to the
ability of capturing signals that arrive at low angles.
I believe it is time for antenna designers to concentrate less on
obtaining gain and instead concentrate more on lowering the TOA.
without the need of excessive real estate requirements.
What say ?

Chris:

I see you got lots of answers, but I don't think anyone mentioned the old WW2 approach. Back in the '40s, police radios
were on 1600-1700 kHz, and mobile antennas were bumper mounted 8 or 10 foot bamboo fishing poles wrapped close wound
with as much bell wire as you could put on them. And they worked amazingly well. I've never seen a shootout between
one and a good loaded whip with a capacity hat, but for whatever reasons, I suspect the bamboo pole would come close.
And it meets your other criteria, cheap. And which, now that I think about it, is equivalent to these fiberglass things
they sell for other bands now. Hmmmm.

Reg, et al:

On the Vertload program, I've been playing with the numbers a bit, and
I've found some things that I have questions from the pro's on..

First, let me explain the situation:

The Truck in question is a Ford LTLA9000. I plan on mounting this antenna 6-8 inches from the side of the tractor on a mount coming off of one of the fuel tanks, which are mounted just below the driver's/passenger's door.

The cab (driving area) of the truck is about 4 feet shorter than the top of the sleeper. The cab is all steel. I use a mag mount 5/8 wave 2M antenna on top of the cab, with great results.

The fuel tanks are aluminum. The straps mounting the fuel tanks to the frame are steel, and mount directly to the frame of the truck under the cab. The sides of the sleeper are steel, up to the level of the top of the cab. The top of the sleeper is fiberglass, with steel runner supports inside.

I plan to mount the antenna off of the fuel tank straps, which will put it roughly 8" to a foot away from the cab, and the steel sides of the sleeper. I have several places I can guy the coil to on the side and top of the cab. I have one or two places I can put PVC standoffs on the cab and sleeper to keep the antenna away from the cab, and to keep it from "flying out" while rolling down the road.

This truck, with a trailer on it and a full load (80,000 lbs gross weight) is capable of traveling at 117 MPH on a straightaway. Faster if I "turn around" the transmission again (no plans on that.. I'm getting too old for high speed "chicken truckin" anymore). I usually keep it down to around 70MPH when the speed limits allow.

So, I've planned on using 1" copper pipe for both the mast and the "whip" at the top, for ruggedness. Inside the coil, I can use some 1" ID PVC for support, and put the 3" coil over those supports, with end caps, etc...

Now, on the antenna, I've found that moving the loading coil up higher on the whip increases the efficiency. So:

1. Does that efficiency increase come at the cost of bandwidth?
2. Does having the load closer to the base increase the bandwidth, if all other numbers (coil diameter, coil length, etc) are the same?
3. Would getting the loading coil above the "steel" increase my chances of making a usable antenna with the bandwidth and efficiency I desire?

I know I'm asking the impossible here; that is a wider bandwidth, higher efficiency, shortened 160M antenna for mobile operations. Like I said, I'd like to get about 10-15KC of usable bandwidth, with an efficiency that'll let me get an ERP of more than a watt or two with 100 watts in. On top of that, I'd like to build it.

Hope this wasn't too much information, and I hope you all can make sense of this.

Try this: run a random wire from an antenna tuner up to the
point where the Isotron Dummy Load is. Enjoy.

Or this: Put a line isolator between the coax and the Isotron
Dummy Load so that the braid of the coax doesn't radiate.
Enjoy (snicker).

I have always thought that if one changed the azimuth angle of a beam
it would improve a number of contact signals, pending the angle they
are reflected from the atmosphere.

Hi Art

I'd say that every little bit helps when conditions are marginal. Even 10dB extra mean pretty well nothing in readability when the signal is already 20dB above the noise, but a few dB *can* make a difference when the signal is in noise. Antenna efficiency and gain in the right direction all helps but it is going to be a compromise. I mean if you want to chat to the "locals" 30 degrees takeoff is better again!

I'll admit that I havent done any huge a amount of modelling on this but (IMO) ground conditions and height over are far more important and are very difficult to design an antenna for all situations. Maybe the trick is to design your antenna for free space for "good" gain and then be able to raise and lower it for the best angles..

For horizontal waves the ground conditions relative to 1 wavelength is of
little concern
Height as always helps with low TOA so one has to determine the average
incoming signal angle
of choice QSO's and design to suit.
Maybe the trick
> is to design your antenna for free space for "good" gain and then be able
> to raise and lower it for the best angles..

Agreed but I would like to see smaller turning radius (moving away from the
boom length mantra ,)
without the necessity for dual driven stacked array This would require a
fixed feed point with
moveable elements for desired TOA to suit desired QSO..
I am sure it can be done, and since 'every thing is
known about antennas' all that is reguired is for a Guru to come forward to
share how it is done.
Regards

Source record: 82846

I say ignore the TOA. (For those unfamiliar with the term, it's the "takeoff angle", which usually means the elevation angle at which the antenna pattern is strongest.)

What counts is the gain at the elevation angle at which you want to communicate. This, in turn, depends on the distance and the propagation conditions. If you need a strong signal at an elevation angle of 15 degrees, it doesn't matter whether the TOA is 10 degrees, 15, or 20 or zero. All that counts is the gain at 15 degrees. And an antenna with TOA of 15 degrees doesn't necessarily have the most gain at 15 degrees of any antenna.

Consider the following three 40 meter antennas: A vertical antenna with about 8 radials (18 ohm ground system resistance), a dipole at 30 feet, and a dipole at 40 feet, all over average ground.

Antenna TOA deg Gain at 26 deg. Gain at 15 deg.

Vert 26 -1.76 dBi -2.72 dBi
Dipole @ 30' 90 (straight up) 2.58 dBi -1.28 dBi
Dipole @ 40' 51 3.9 dBi 0.32 dBi

-- Which one has the lowest takeoff angle?
-- Which one is the best for communicating at 26 deg. elevation angle?
-- Which one is the best for communciating at 15 deg. elevation angle?

What does the takeoff angle have to do with which antenna is best?

> I don't see that! would not the S/N stay the same?

Well to tell you the truth this was one of those "told by someone else" things that I never did get around to proving myself (thinking it was general knowledge) I have of course noticed it on 2M FM where the recovered audio S/N falls off very rapidly as the usable senitivity of the radio is reached. In that case a 1 or 2dB signal increase can make the difference between readable 1 and readable 4. I have a funny feeling the discussion I heard on the topic may have been on front end NF of VHF/UHF receivers where a 1dB lower number there yielded a much larger dB result. Note this was for SSB. I have some work to do here understanding this. When I look at building another preamp for 2/70 I'll do it then!

However if the noise is -110dBm and the signal was -114dBm, the margin (s/n) would become less (of a negative number) when the signal level is increased. You may not be able to resolve it but you can measure the difference. You can of course use DSP techniques to resolve signals weaker than noise. WRSS60 for example will enable you to resolve signals 26dB below the noise level. FSK441/JT44 is another example of signal below noise reception.

Something about brewster angles and phase reversal in horizontal but not vertical polarisation? (Note I work in IT, not RF!) I always thought that the poorer the ground (eg sand/clay) the higher the takeoff angle and over seawater was the lowest one could attain. (Keep in mind that VK dropped CW earlier this year and I was one of those that has been playing VHF+ for the last 25 years!)

> Agreed but I would like to see smaller turning radius (moving away
from the

I would also expect that F/B & F/S are major contributors to design to. Very handy when you neighbours son a few miles away wants to tune his VW engine! I like the idea of a quad, simply because of its smaller turning radius!

I once had a think about ways to tune a 3 element quad for best F/B. Maybe some way to roll the wire up on a small motor shaft or tune it with some C on the end of some tuned length feeder? Didnt figure out an easy way to change the element spacing though. Maybe bending the spreaders would have a similar effect of changing the feedpoint positions on a stacked array?

You could also change the length of the phasing sections for a dual driven stacked array - rather than moving the feedpoint. If I was experimenting with this idea I'd probably start (modeling) with 3 parallel horizontal dipoles arranged such that when viewed from the ends the (end point) shape was a triangle. All would be fed in parallel but with different phase relationships between them.

> I am sure it can be done, and since 'every thing is

> share how it is done.

Not me sorry. If however I stumble onto something that defies all the theory and works better than anyone else, this NG will be the first to know - and I'll make the design like GPL software! Free...

Cheers Bob VK2YQA

That would depend on the desired contact. If you want 80 meters DX,
you want a very high antenna, if you just want to talk to your local
buddies, a lower antenna provides a better NVIS.

Verticals provide better omni-directional pattern but a slanted dipole
provides better directivity than a vertical.

Beams are obvious.

Use line of coax appr. 2 m long for 400 Mhz. Power it up from Generator (CV). Attach quarter wave radiator on another end (bare piece of wire).

You expect to have power running back along the outside of the coax shield.

How to see it - make a detector: pick up coil - several turns of wire small radius. Load it on diode (LED works too). Measure voltage across the diode.

when you move detector along the coax, you will see nulls and maximums, approximately half wave length from each other (may vary considerably depending on your setup.)

now add ferrite choke at the antenna end of the cable. Observe change of amplitudes you see with detector. Add more ferrite.Observe how efficiency of your choke improves when it's length increases.

...
it is all fine up to here - you observed operation of the ferrite choke. Is it a good balun - depends. Unlike coaxial sleeve the ferrite choke absorbs the energy - it is not sending it back to the antenna.

Hi All,
I've built a 30M Jpole using dimensions from the Jpole calculator in Hamcalc and using 300 ohm twin lead for the matching section.

It seems to resonate about right, but the SWR is 2.2. I'm using an Autek RF-1 analyser, and want to know if there's any way to determine what changes to make to get a lower SWR? I don't have a lot of the twinlead left, and don't have enough time to get more, so cut-and-try isn't the best solution.

Hoy!

Thank's for the very interresting link to the isotron reviews. It's nice to see that citizen's band 's still living on...
Everyone decided to buy one and was pleased by the SWR... but none of them seemed concerned about radiation patterns and loss (negative gain?), nor by the classical "how does it work" question.

No they were all happy to kick 50W power in it to make DX with the guy in the village nearby... DX begins at your door... But never heard about ground wave propagation.

Nevermind... As far as everybody's happy, it's all good!

Probably not a J-pole shorted at the bottom but a J-pole
(Zepp) open at the bottom? The trouble with a Zepp is
there are no adjustments except length. With a J-pole
shorted at the bottom, you move the feedpoint until you
find the 50 ohm point. With the open ended J-pole (Zepp)
the 1/4WL bottom section is a fixed transformer.

Your feedpoint impedance is probably 110 ohms (don't think
it would be 23 ohms but it might be). Installing a 1/4WL
piece of 75 ohm coax between the feedpoint and your 50 ohm
coax should give you a near perfect SWR. For a piece of 75
ohm coax with VF of 0.66 (RG-11) that would be about 12.7
inches.

Let me have a shot at it, Roy.

<possible blather alert!>

Perhaps there is confusion by some people with the idea that the takeoff angle. I suspect that a lot of people think of their RF leaving the antenna as a "blob" that leaps out at some desired or undesired angle.

Instead, the RF is heading off in all directions, with some angles having more relative power.

So even if an antenna has a lower TOA, it might be less gain than an antenna that has a higher TOA has at that angle.

An inefficient antenna with a low TOA can be less efficient at that low TOA than a more efficient antenna with a higher TOA is at that same low TOA.

Oy.

Maybe a picture is worth a thousand words. Here's a comparison
radiation pattern for my 130 ft dipole Vs my 40m vertical with
elevated radials. In the dipole's favored direction, it's TOA
is greater than the vertical's yet the dipole radiates more
power than the vertical even at the vertical's TOA. Here's the
picture: http://www.qsl.net/w5dxp/dipvsver.htm

When band conditions are excellent, even a dummy load will work. Most non-amateurs and many amateurs don't understand this. In some cases if an antenna works at all, it is great. Anything works better than nothing. However, those of us who experiment with antennas quickly learn that the throw of a switch will tell us how much better one antenna is over another.

To some of us, an economical antenna that doesn't attract attention is better than a more expensive high gain antenna. To some of us, only the best performance antenna will suffice. A QRPp station can not afford to have a high loss antenna where as a QROo station can overcome the losses with power.

Hi m

Don't waste your time!

More often than not there is no continuity in cast iron waste piping.
Joints are packed with Oakum and then lead poured in the bell to seal
out sewer gasses. The Oakum acts as an insulator and the lead is not
much better than a cold solder joint, electrically speaking.

If a vent stack did have a good ground and ever did take a good
lightning hit there would be lead flying all over the place.
You rarely hear of a vent stack being hit BECAUSE it is a very poor
ground, if grounded at all.

I used a mag mount antenna on the right front fender and brought the coax under the hood and then through the firewall into the cab. The hood had enough gap to allow the coax in without kinking or mashing. I secured everything under the hood with cable ties. I used a 1/4 wave (I think) about three feet high. And I have used one of the very short antennas, about 19 inches high with very good results. Comet, Diamond and Hustler all make good antennas.

Good luck, jimbo

Someone correct me if I am wrong, but isn't gain derived by narrowing
focussing all the energy into a more narrow path?

Besides, TOA is important to the location of an antenna in respect to
its relative position to the ground and the surrounding terrain.

I have heard that people surrounded by mountains prefer a 1/4 whip on
their cars for 2 meters and up when trying to hit repeaters due to its
higher angle of radiation, but in the flat areas, the preferred
antennas are the 5/8 wave etc due to its horizontal gain.

Being on the side of a hill, I can't use an antenna at roof-top level
with a low angel of radiation as there isn't enough power to get the
signal through the miles of land mass under my neighbor's houses.

I did an experiment when I first received my General license to see if
I could sign into the GA SSB NTS Net. I rolled out a spool of wire on
the ground approximately 1/4 wave for 3975 kc. Without a tuner I was
able to get acceptable SWR and checked into the net. I wasn't the
strongest signal but I did well enough to hold several QSOs. It
wasn't as good as my dipole when I raised one, but it worked better

than my 40 meter dipole at the time.

I believe that a horizontal dipole will have about the same TOA as a vertical dipole when both are sufficiently high. However, the dipole is more bidirectional and the vertical is omni directional. Therefore the horizontal dipole may display some gain broadside over the vertical.

I believe that Cecil's picture reinforces the idea that on HF especially, the TOA is largely affected by the antenna's elevation above ground.

However, I was reading in CQ or QST last year about a DX operator who uses verticals near the sea and wins his contests because of his antennas. He finds the best location for his antennas near the ocean. I believe he said he had tried beams before but there is an ocean effect that makes the verticals better suited for his operations.

That same vertical would be lousy for me as my house is on a hill that forms a very close valley.

I used a Taylor Radio vertical years ago in this yard and it sucked. However, when I used it in Charleston and Jacksonville, it was fantastic (not near the ocean).

Another DX operator suggests that most people will have a better chance of communicating with him if they use a slanted dipole pointed in the direction of their QTH. The angle of radiation and gain make it a great DX antenna.

Different antennas work differently depending on their locations. I think your better question would be, what is the best antenna for my QTH and operating style?

Buck, in my posting I refered to 20 meters and also the incoming angles and
average signals thereof coming from Europe. Thus my interest was in the
lower half of the main lobe. The thickness of the lobe of the lobe would
thus not be important,
only the contour of the underside of the lobe. It is this portion of the
lobe where a DXer referers to the fact that a db means a lot as opposed to
adding a db gain to angles contained within a lobe. Note that the thickness
of the lobe can vary even tho both anternnas may have the same take of angle
as can be seen by comparing a monster boom length antenna to that of a
stacked beam which admittedly has a feed point which is very high. When
comparing these two types an optimum would be a low feed point (1 WL) with a
small turning radius with means to compress the main lobe downwards for
those DX
signals arrive and where the 'silly' db becomes everything
Regards
Art.

Maybe some good news - I hear that BPL is showing up as
blips on radars.

If you obtain a normal toroid type transformer with say 6 connections
(female connection)
for various so called standard ratios you can connect these to a rotary
switch which then allows you
to obtain multiple ratios over and above those listed on the transformer.
One of these at the top of the tower and driven by a stepping motor should
cover all your needs.
Regards
Art

I would say this whole idea has been sold by people more interested in getting the money of ignorant investors that building a workable system. BPL will likely die shortly after implemenation if it ever gets off the grond at all. The cost is just to high for it to be viable.

On Sat, 29 Jan 2005 10:52:05 -0500, Buck <iam@this.site> wrote:

>Someone correct me if I am wrong, but isn't gain derived by narrowing
>focussing all the energy into a more narrow path?

Hi Buck,

Thanks for the invitation (but we are a rabble of party crashers anyway). What you say about narrowing to achieve gain is a useful analogy, but there are some problems on down the line:

>Besides, TOA is important to the location of an antenna in respect to
>its relative position to the ground and the surrounding terrain.

True, except to invert the inference: location and terrain is important to the TOA (put the horse before the cart, in other words).

>I have heard that people surrounded by mountains prefer a 1/4 whip on
>their cars for 2 meters and up when trying to hit repeaters due to its
>higher angle of radiation, but in the flat areas, the preferred
>antennas are the 5/8 wave etc due to its horizontal gain.

This reveals the problem with testimonial in place of measurement. Unless you are in the Grand Canyon, you stand a chance of communication at a very much greater distance to a mountain than you are to another rig on the same plain. Even an HT has enough power to communicate with a sattelite (or space shuttle). This reveals that power is not the problem for considerable distance. However, at this frequency (2M) line of sight on the plains is not that very far away (less than 5 miles with your HT in your hand). On the other hand, if on the plains you can see a mountain 50 miles away, you are as likely as not to be able to talk to it to (presuming a repeater inhabits its peak).

Hence the gain differential of quarterwave and 5/8ths is not necessarily required for the Power nor the TOA - other issues are at work. When the issues are not discussed, nor investigated, then changing the antenna system from one to the other may resolve that hidden issue and the difference attributed to the antenna - voila! testimony offered.

>I did an experiment when I first received my General license to see if
>I could sign into the GA SSB NTS Net. I rolled out a spool of wire on
>the ground approximately 1/4 wave for 3975 kc. Without a tuner I was
>able to get acceptable SWR and checked into the net. I wasn't the
>strongest signal but I did well enough to hold several QSOs. It
>wasn't as good as my dipole when I raised one, but it worked better

>than my 40 meter dipole at the time.

You have a bad habit of comparing the qualities of one antenna on one band to the qualities of a second antenna on another band. This is called testimonial, and it is not very useful in demonstrating correlations. Trying to draw two different observations under the same umbrella of discussion does not lead to any general conclusion.

Your 80M antenna on the ground would match, certainly when so obviously in the grip of ground. You could have probably qualified that installation to match at nearly any frequency - if we confine the goal of matching to present no reflected power. A ground hugger so qualifies and the ground is content to absorb (without reflecting) all the power you pour into it.

What you fail to compare is how it worked "better" than your elevated 40M: how far were you working 80M contacts? The ground laid antenna was used in Desert Storm for just this quality and it provided useful contacts in missions there, but they were not interested in skip.

>However, I was reading in CQ or QST last year about a DX operator who
>uses verticals near the sea and wins his contests because of his
>antennas. He finds the best location for his antennas near the ocean.
>I believe he said he had tried beams before but there is an ocean
>effect that makes the verticals better suited for his operations.

This, again, is testimonial. However, it is often attended with compelling testing and theory that dovetail. The simple explanation is that the vertical's radiation is constructively reinforced at low angles by the sea, a horizontal's radiation is destructively combined by the sea at low take off angles. The difference at very low angles is far in excess of a 'little' db.

If you look over your shoulder to all that sand behind you, then that same vertical becomes a miserable performer in comparison to those beams turned to follow your eye.

>Another DX operator suggests that most people will have a better
>chance of communicating with him if they use a slanted dipole pointed
>in the direction of their QTH. The angle of radiation and gain make
>it a great DX antenna.

It's surprising how many Hams have missed this gem of wisdom. It must mean that
1. We are a particularly dull and stupid lot;
or
2. It doesn't really offer all that much for the effort.

Hi OM,

BPL suffers the same problem: "The Last Mile." However, in rural
America it is not 1000 customers in the last mile, it is the 3
customers in the last 10 miles.

BPL has all the smoke and mirror investment potential as a new
millennium dot.com. WiMax will bury this fizzling comedy.

For a disparaging view of WiMax:
http://www.eweek.com/article2/0,1759,1668327,00.asp?kc=EWYH104039TX1B0000665
It is obvious that even the most restrained and pulled back design
wins hands down over BPL for BPL's proposed customer base.

Amen.
Let us use TOA for the elevation angle where an antenna's pattern is
strongest and ATOA for the actual elevation angle used over a long HF path.

At least from 7 MHz to 21 MHz, when DX ionosphere propagation is likely
the ATOA is between about 12 degrees and about 2 degrees. When comparing
antennas to be used for HF DX contacts, it is appropriate to note the gain
at 3, 6, and 9 degrees as being the numbers to compare. The actual TOA (as
defined above) is only interesting.

That said, it is possible to have a single horizontally polarized
antenna that is so high that it suffers in comparison to a lower antenna for
ATOAs of about 10 degrees (by more than the one db that is being talked
about). For one horizontally polarized antenna to be used for DX contacts
the desired heights are two to three wavelengths above earth.

If one can use a plurality of horizontally polarized antennas,
interesting results are possible. For instance: on receive, combining a
lower second antenna with a tall first antenna can effect the approximate
cancellation of the second lobe. The second lobe has a high TOA and can
contribute significantly to the noise and interference received from
relatively short distances. Nulling the second lobe can significantly
increase the received SNR.
For closer spacing of multiple antennas, one can effect more gain than
that of one antenna - with trade-offs.

I emphasize what has been said by Roy and others: TOA (as defined
above) is interesting, but it is not the most important number for DX
contacts.

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

Some people believe that belonging to a local church, temple, mosque or synagogue will get them to Heaven.

Others believe that water baptism, obeying the ten commandments or just being a good person will get them to Heaven.

There are many other beliefs as well, but the good news about God's way to Heaven is found in the Holy Bible.

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins. After Jesus was placed in a tomb He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Bible says, "For the wages of sin is death, but the gift of God is eternal life through Christ Jesus our Lord." (Romans 6:23)

This verse in the Bible says, "For ALL HAVE SINNED, and come short of the glory of God." (Romans 3:23)

This verse says, "But God demonstrates his own love for us in this: While we were still sinners, Christ died for us." (Romans 5:8)

In this passage the Bible clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

Salvation is not a reward but a gift. The Bible says it this way, "For it is by GRACE you have been SAVED, through FAITH and this not from yourselves, it is the GIFT of God." (Ephesians 2:8)

Nothing in the world is more important than your eternal destiny.

The Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you have not yet made a decision to be saved, please do so now before it is too late. The reason why it is so important to be saved now is because you do not know exactly when you will die. You may die prematurely in a traffic accident, terrorist attack or some other way before you get another chance to be saved.

The Bible tells us that we will spend eternity in Heaven or a place of eternal torment called Hell. It would be terrible to die and go to Hell when all you have to do is accept Jesus Christ as your personal Lord and Saviour.

Some people that have already made Jesus Christ their Lord and Saviour worry about losing their salvation. The Bible teaches Christians that we can never lose our salvation no matter what happens.

The Bible says it this way, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus Christ, the Righteous One." (1John 2:1)

Yes my friend, Jesus Christ is able to save you and keep you saved.

Please tell your family and friends, thanks!

Have a great day!

I am building a new house. I need two coax runs inside the house for two uses. First, for 2 meter, 440 MHz dual band. Second for 2-30 MHz HF. I am considering using RG213/U for both runs. I know this coax is suitable for 440 MHz on runs less than 100 feet. Would there be any problems for the 2 meter or HF using this coax? Or are there any suggestions for this project?

Thanks, jimbo

Source record: 82782

Yes I just installed a 100' run and a 50' of 9914F "direct bury" coax for VHF and HF respectively. This coax is lower loss than 214 and much more robust in it's environmental qualities and can be buried directly. I purchased ready made coax assemblies with silver-plated Amphenol PL259's attached from RadioBooks Radio Ware

1. http://radiobooks.com/products/ca9914f.htm

9914F is very nearly as lossless as 9913 but is more flexible and can be directly buried.

Ok, Art,

I think I am with you now. I just re-read all the previous posts. Roy Lewallen first referred to the 40 meters and I think he introduced the picture of the angles from a vertical and a dipole.

Sorry to have been so slow picking up on this, and thank you all for your patience with me. With all this discussion, I am learning. I echo back my thoughts at the time that may be subject to change upon correction or even possibly due to misinformation, hihi.

I have been studying antenna theory for a while now, off and on. Not like a college professor, just on my own. Let's start by getting back to your original post.

You are interested in DXing on 20 meters in which most signals come in at 11 degrees or less. Therefore antenna designers should focus their attention, not on antenna gain, but on getting the gain to the incident angle of radiation. You mentioned that Amps turn out to be of little help if the antenna angle is wrong. (I'll save the amp for another discussion and deal with the antennas.)

I have been studying about antennas for a while now. (not like a college professor, probably more accurately I have been reading a lot.) I understand what you are saying about the amplifier. From my experience I have learned a simple truth. Either one has the propagation to make a contact, or one doesn't make contact. Last year I totally surprised myself when I called a DX station in a pileup and he answered. I was running an FT-817 into a dipole about 65 feet high. There have been times I couldn't break a pileup with a 400 watt Swan on the same antenna.

Getting back to your topic, from what I understand, the terrain and antenna elevation are as, or more, important in establishing the angle of incidence as the antenna is. IIRC, a Yagi has a recommended minimum height above terrain for optimum operation. I believe that 20 meters is 125 feet.

BTW, I am curious to know, from where did you get the information that the incoming signals are at 11 degrees?

Speaking of Yagi's and gain, I know that the gain (and inversely the bandwidth) of a yagi is increased by extending the spacing between elements. A wide spaced gives a little more gain than narrow spaced elements. I believe it also narrows the beam width of the signal. I don't think it affects that TOA, though, except maybe by its relationship to the ground and its surrounding terrain.

The original poster asked for opinions from those that owned the isotron antenna -- we gave him that.

Now if he had asked for antenna measurements on an antenna range and comparisons to other antennas -- that is a different question. And I don't know where he would have found that answer.

As far as statistics -- fact is 3 out of 10 accidents are caused by drunk drivers -- thus 7 out of 10 are caused by sober drivers - guess we ought to get em off the road - huh

It sort of depends on how much loss is acceptable to you. 9913, for example, will have about 50% of the loss that 213 gives you at VHF/UHF frequencies. Remember, that the worse the mismatch (SWR) the higher the loss -- the tables you see assume a 1:1 SWR, so real world losses are always higher than what the tables show.

To directly answer your question -- if you are happy with 213 for 440, you will be happy with it at 144 since the losses will be lower at a lower frequency.

Not that it is likely to be relevant, but I use 9914 BuryFlex here since to make my wife happy, I run the coax underground. It should be pointed out that I don't have an antenna for anything above 6m.

Good luck

Hi Buck,

This is fine.

> I don't think it affects that TOA, though, except maybe by its
>relationship to the ground and its surrounding terrain.

It is unlikely that anything you do in such a small footprint will bring any geometric change that brings even a perceptible change to the TOA. However, by simply increasing gain, the entire lobe structure of the antenna increases (same shape balloon, but now a larger balloon) which does impact the TOA; but not its angle, instead more its magnitude. This, in a sense, was the comparison Roy was drawing upon with the different examples.

In a sense, increasing the antenna gain (all other factors held constant) would be indistinguishable from simply boosting the transmitter gain (or adding an Amp).

Let me re-iterate what you said, assuming I understand it.

Art is saying that it is better to have a more accurate TOA than the last db of antenna gain, but you are saying that a better s/n ratio (as handled by the antenna) is better than the last db of gain.

Of course, Art started his statement with something about a person turning up their amplifier and having no better results. Therefore he must also be considering being heard as well as hearing. I would think that an amplifier will, for the most part, increase the radiation strength of every angle radiated at all by the antenna. If the amp represents a 6dB gain over the radio, it will represent a 6 dB gain in the any direction in which the lobe points. At least for the transmission, that should provide the 1 db difference we are talking about.

This doesn't address that time of day in which the west hears from the east in one way propagation.

Correct me if I am wrong here.

Since you're still serious about this, if possibly from a lower floor....

The waste-vents, if cast iron, will have steel pipe hangers clamped to the building's structural steel at every floor, with the first one being right under the roof. It might very well be an excellent static ground. Without meggering the vent, you could still determine DC resistance by running an extension cord from the rooftop utility room outlet to a vent pipe, and measure resistance between the electrical ground and the vent.

Baluns, in general, are the least important component in HF antenna systems.

The first question to ask yourself is why do you think you need a balun?

If you can't think of a reason then you don't need one.

If you CAN think of a specific reason then ask yourseslf, or somebody, what type of balun do you want. There's very little to choose between them.

But to get anywhere at all you MUST decide in terms of numerical and statistical quantities.

Please be specific. Or just copy the widely distributed, plagiarised, old wives, average recommendations.

And beware of balun salesmen and sales ladies. There are more than one means of making a living in our capitalist system. And everybody has a human right, irregular or not, to make a living. Thus confusing baluns. ;o)

In conclusion - what's your numerical problem?

Just to clarify -

The angle of elevation of the radio path between points A and B on the Earth's surface is always a constant which depends purely on the Earth's geometry and the number of hops.

It has nothing to do with the radiation patterns, beam widths of either the receiving or transmitting antennas, vary as they may.

There may of course be short term variations due to ionospheric effects.

Dear Buck (N4PGW):

I am having a difficult time finding what I thought that I said in your paraphrasing. Your bio on QRZ.COM does not indicate an interest in DX, so it is possible that all of my comments were misdirected.

Perhaps the essence of what I was trying to say, in addition to agreeing with Roy, is that it is desirable with (single) horizontally polarized antennas at HF to have as much gain as possible appear in the direction that is expected to be used for DX contacts. In turn, that suggests that it is desirable to have a height above ground (or above the applicable "refection" area) be between 2 and 3 wavelengths.

I do not recall writing anything about power amplifiers or something called "one way propagation."

Jimbo:

More loss but less expensive. If the run is short and the mismatch is not too bad, you can save a few dollars by going with the 213 and accepting slightly higher losses. Just talk louder.:)

I think you and I are in agreement except for what Art believes. (see
his statement below:)

>I believe it is time for antenna designers to concentrate less on
>obtaining gain and instead concentrate more on lowering the TOA.
>without the need of excessive real estate requirements.

He agrees that the antenna is better as it improves receive as well as
transmit, but I can't see the TOA being more important than the gain
unless it is really off by a long way. An NVIS antenna has a
different purpose than a DX antenna so he would need an antenna that
fits his needs. I am not sure what would reduce the TOA over a Yagi
unless it is a Yagi pointed downward.

Maybe what we need to be doing is asking Art what his situation is and trying to find the antenna that best fits his needs. I can't help but think that this question arose because he can't seem to find the antenna that helps him make successful DX contacts.

I used a TA-33JR for years. It was a fantastic 3 element beam. It was small, fit on my roof and could be turned by a RadShak TV Rotor. Even though it wasn't the ideal height above ground, it made a world of difference chasing mobiles for the WA counties award.

I try to learn a lot about antennas. I don't claim to be an expert and certainly don't want anyone to think I am trying to make Art (or anyone else) look like they don't know what they are talking about.

BTW, Art, have you looked at the N4GG antenna? It is on the ARRL site for members. I built one and didn't understand it so I took it down and made a new antenna. Then I got the details of it, but it was promoted as being a low angle of radiation. I don't know the degrees, though. It was certainly a much quieter antenna than the dipole.

I talked to N4GG by email. He is a real nice person.

Good luck,

Buck

1659. Vertical vs Horizontal

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-30 02:04:23 UTC
From: Buck <iam@this.site>
Message-ID: <eofov0dv0doh78qlssda8bhcsk5l9ha5g2@4ax.com>
Source record: 82798

I occasionally chase counties when I am sitting at my desk doing other things and have the radio available. Right now I am using a horizontal dipole antenna to make contacts. The downside of this is that many times I can't hear the mobiles or they can't hear me.

I am thinking that I might be able to improve my contacts by using a vertical antenna since most mobiles use vertical antennas. I have heard that once the signal bounces off the ionosphere, polarity isn't as important as it is for local communications. However, when I was assembling a 2 meter dipole antenna, I held it horizontal and turned it vertical. I saw the s-meter go from nothing to s-7 and the repeater go from silent to full quieting when I did this. I can't help but wonder how much difference it will make with the mobiles.

Thanks for the comments.

The paragraph you quoted is the paragraph I reiterated what I thought
you were saying. All that follows was not from you, but a followup
continuing the topic.

As for DXing. I don't chase it, but I don't turn it down either. We
do seem to be in agreement that TOA isn't the most important factor.

{Break from that}

I have heard where antennas, beams in particular, have been mounted
too high and thus not been as good for the contact. I don't remember
the numbers, two to three wavelengths sounds right, but there seems to
be an optimum height for beam antennas.

Art first mentioned the amps and I threw in the one-way propagation
statement, which probably neither of which really contributes to the
real question for discussion.

Message-ID: <cchov0psb89gnbb33j6pnvq113t2gp66ro@4ax.com>
Source record: 82803

Here is the URL to a home-brew 4:1 balun that should work from 160-10 meters. I am interested in a 6:1 balun.

Since I have the materials for this balun, is there a similar one for a 6:1 or is there an easy way to convert this to varying ratios of baluns. For example 'double the number of turns for 50% more X:1 ratio'?

Thanks in advance

It's important to realize that at HF (where atmospheric rather than receiver noise dominates), different criteria are important for receiving than transmitting antenna improvement.

If you simply increase the gain of an antenna without changing the pattern (by, for example, improving the efficiency of a vertical by adding more radials), it improves the S/N ratio at the station you're talking to, but it doesn't help the S/N ratio at your end. The reason is that both of you are getting noise from elsewhere. When you increase your gain, it improves the signal at the other end, while the noise at the other end stays the same, hence the S/N ratio improvement. But the gain increase causes both the signal and the noise to increase at your end, both in the same proportion. So you've improved your transmit effectiveness but haven't improved your ability to receive. You've done no more than you would by turning up the volume control.

The only way to improve your ability to receive at HF is to improve the directivity of the antenna, so it has less gain in the direction the noise, or some of the noise, is coming from compared to the direction of the station you're talking with. Deep pattern nulls are usually an important factor in doing this. If the signal and bulk of the noise both come from the same direction, you're stuck. The pattern makes no difference for transmitting, only the gain in a single direction. (I'll ignore the possibility of multipath propagation or surface/sky wave interference for this simplified explanation.) But for receiving, the ability to have different gains in different directions is important. Because the absolute gain isn't important, a small and inefficient but rotatable antenna with some good nulls can be an excellent receiving antenna.

At VHF/UHF, where the noise primarily comes from the receiver front end, antenna gain helps the S/N ratio for both transmitting and receiving.

Let me encourage you to build a vertical antenna and arrage a switch so you can switch back and forth between it and your dipole. Be sure to use a current balun or two in your dipole feedline so it doesn't become part of the test.

Here's what I think you'll find, as I have when comparing a vertical to a horizontal antenna. At times, one antenna will be spectacularly better than the other -- by 20 dB or more. After a while, maybe a minute or so, the signal on the good antenna will fade, and when you switch you'll find that the other antenna is now a lot better than the formerly good one, by about the same amount. This cycle can go on for quite a while. This is likely due to polarization rotation (although multipath can cause a similar effect, if the antennas are spaced far enough apart); whichever antenna has the right polarization for the moment will be much better than the other.

I don't believe you'll find any spectacular overall improvement by using the vertical.

When doing these tests, don't make the mistake of assuming the units on your S-meter are some particular number of dB, unless you have the abililty to actually measure them. Any assumption you make could be WAY off.

> unless it is really off by a long way.
But Buck that is exactly what I am talking about. Just think about what types of antenna
can be considered a band opener. Somebody mentioned a 150 foot boom yagi which tho
it has lots of gain it is at a low height. I suspect the lobe it is projecting will be around 13 degrees
and the lobe will be fat suchg that the lower portion of the main lobe may well encompass a 10 degree
signal. Another band opener will be say a three element antenna at a height of say 150 to 200 feet.
The three element antenna is not a ground shaker but the lobe is made lower than a normal
height antenna thus even tho the antenna is relative low gain this low gain is directed at a low angle
say 10 to 11 degrees that can intercept signals just as the band is opening.
Another band opener is vertically stacked three element beams solely because there is three db
gain to be had purely by stacking that can be added
to the uppermost antenna which also lowers the interception angle area by virtue of a fatter lobe.
Now look at the band when it is well established, most antennas will now intercept a lot of the DX signals
but at the same time many of the band opening antennas may well fail to hear the signals as the signals
may well be coming in at a higher angle which coincides with the null supplied between the first and
second lobe . In all of this you must take note of what Reg said in that communicating signals must have the same hop distance which revolves around lobe interception and not gain. If the lobe intersection of the two stations vary by say a few hundred miles no amount of extra gain is going to make communication possible.
I am a member of the RSGB and not the ARRL.
Regards
Art

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

Some people believe that belonging to a local church, temple, mosque or synagogue will get them to Heaven.

Others believe that water baptism, obeying the ten commandments or just being a good person will get them to Heaven.

There are many other beliefs as well, but the good news about God's way to Heaven is found in the Holy Bible.

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins. After Jesus was placed in a tomb He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Bible says, "For the wages of sin is death, but the gift of God is eternal life through Christ Jesus our Lord." (Romans 6:23)

This verse in the Bible says, "For ALL HAVE SINNED, and come short of the glory of God." (Romans 3:23)

This verse says, "But God demonstrates his own love for us in this: While we were still sinners, Christ died for us." (Romans 5:8)

In this passage the Bible clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

Salvation is not a reward but a gift. The Bible says it this way, "For it is by GRACE you have been SAVED, through FAITH and this not from yourselves, it is the GIFT of God." (Ephesians 2:8)

Nothing in the world is more important than your eternal destiny.

The Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you have not yet made a decision to be saved, please do so now before it is too late. The reason why it is so important to be saved now is because you do not know exactly when you will die. You may die prematurely in a traffic accident, terrorist attack or some other way before you get another chance to be saved.

The Bible tells us that we will spend eternity in Heaven or a place of eternal torment called Hell. It would be terrible to die and go to Hell when all you have to do is accept Jesus Christ as your personal Lord and Saviour.

Some people that have already made Jesus Christ their Lord and Saviour worry about losing their salvation. The Bible teaches Christians that we can never lose our salvation no matter what happens.

The Bible says it this way, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus Christ, the Righteous One." (1John 2:1)

Yes my friend, Jesus Christ is able to save you and keep you saved.

Please tell your family and friends, thanks!

Have a great day!

Dear Reg:
You may have written the first sentence below towards the end of
engaging in your favorite evening activity of experimental wine evaluation.

As you well know, the ATOA (actual take off angle) of a fixed DX path
varies quite a bit from time to time and frequency to frequency. Indeed,
when clarity returns in the morning, you will recall that the ATOA at A can
be quite a bit different from the ATOA at B.

Truth in wine depends on the amount consumed and the time of day/night.

From URL:
http://www.astronantennas.com/polarization.html

On line-of-sight (LOS) paths, it is most important that the polarization of the antennas at both ends of the path use the same polarization. In a linearly polarized system, a misalignment of polarization of 45 degrees will degrade the signal up to 3 dB and if misaligned 90 degrees the attenuation can be 20 dB or more.

For HF work (skip) I use both vertical and horizontal antennas and switch
back and forth for the best signal.

Sometimes it is the vertical antenna -- sometimes the horizontal

As discussed here under "A little dB extra gain" the take off angle enters
into the picture also.

See my previous post for line of sight considerations

Ah, shortsighted Jimbo:

Consider these: Damage to one of the coaxes, for example. And what about rotator cable? Or suppose you get interested
in another band or mode? My advice to people building new homes is to run conduit wherever you are going to need it,
and make it as big as practical. Then you can pull whatever coax you need, and upgrade when you feel like it. Or at
least be sure there are accessible pull wires wherever they might be needed. And coax has a limited lifetime anyway.

Fair enough, I can't know where everyone is on the internet. On the
air, I get the advantage of having their callsign. I'll be glad to
send you the antenna design if you wish. (I see that isn't your
problem here).

>Regards
>Art
>

It appeared to me that you were looking for that lower lobe, not the higher one when the band opens. The longer the beam, the narrower its pattern is, and like better the rejection from other directions (f/b, f/s rejection, etc. I took that as an understood.))While answering both you and in part, Roy,)

from the OP:
>Fact is that most long distance signals on 20 metres come in at angles
>of 11 degrees or less where as the 'normal' antenna has a TOA of around
>14 degrees.
end quote.

I was under the impression that you felt a need for designers to find a lower TOA. closer to ten or eleven degrees. I am confused, there can be no doubt of that in your minds at this point I am sure :). I do realize that at least in a yagi, as you increase the forward gain (f/b and s/b ratios), generally by adding elements that it narrows the forward lobe horizontally and vertically. A 150 foot boom (say 20 elements for example) beam might be perfect for picking up the lower angle, which is what I thought you were looking for. The three element beam will bring in higher angle signals as the lobe will have a higher angle. A dipole will likely have even a higher, possibly a NVIS angle. As for being quieter, I didn't define it but I mentioned that the N4GG antenna was much quieter than my dipoles. It also has a low angle of radiation, which fits very well with what you and Roy are telling me. It doesn't have a high gain, in fact the designer doesn't even try to calculate it except to say it is a little higher than a dipole. He also said it was designed for the DX and not to expect to chat with many nearby stations.

For a small real estate layout, I imagine that the N4GG can be used with a dipole or small beam for continuous DX operation. Of course the N4GG antenna is larger than a dipole. It is one wave long and has quarter wave legs hanging off it.

... from the OP
>I believe it is time for antenna designers to concentrate less on
>obtaining gain and instead concentrate more on lowering the TOA.
>without the need of excessive real estate requirements.

Are you looking for a small antenna that will pick up the DX before the other DX hounds start piling up?

Yes.

If you are going to use it at VHF, match the lengths electrically. At HF mechanical length is good enough. And, you do
understand that they are to be connected in parallel, both centers tied together and both shields, right?

Thanks. My determining factor will be making the contact when I am up
for it. Too many times I have heard an s5 or better signal but by the
time it was my turn to call, or the pileup dies down, I can't hear the
mobile. That may be the answer.

I once considered phasing the vertical and horizontal together, but
from everything I read, the advantages of one over the other often
have to do with noise not picked up due to polarity. Horizontals have
some noise, and verticals have different noise, but a combination of
the two would have it all.

Since I am dealing with 20 and 40 meters mostly, I would only concern
myself with the 20 meter vertical. 40 doesn't seem to have the
problem. It seems that if I hear them on 40 I can work them. On 20 I
might get a 5-7 reply to a 22 report or vice-versa.

If I hang the vertical here, the top will be about 65 feet above
ground. The dipole feedline will be about 15 feet away and the center
of the dipole about 50-55 feet high. I doubt they will interact with
each other.

Thanks for your comments.

OK. When the meter lamp in my Kenwood TS-430S burned out recently,
I substituted a 12V replacement from Radio Shack. So, are bulbs
rated the same way? Certainly, it would appear auto bulbs are,
but what about wheat lamps?

Rob

Yes, that is exactly what I said and what I mean.We need to get away from
the long boom high gain aproach which cannot be used in many places and
look at other aproaches to getting a lower lobe trajectory with a small
turning radius.
Some will say that is impossible where as I would say it is possible when
open minds
are turned to the task.
Just think of what I could be describing, a 20 metre antenna with a
ten to eleven degree TOA, turning radius of a conventional dipole and a
feed point
of something less than 75 foot high. Now thats good for small real estate
and a light duty rotor
tho the U.K. authority may baulk at the height. I have built very long boom
yagi.s. for 20 M
some with a couple of reflectors and some with as many as 13 elements but
this direction is limited
by minimal advances compared to complexity, thus my statement as to what the
hobby needs
for it to grow
Regards

much
> better than the other.

Thats pretty close...They flip flop back and forth...
>
> I don't believe you'll find any spectacular overall improvement by
using
> the vertical.

Depends on the length of the path, and the frequency. On 40m at night,
the
improvement using the vertical is spectacular *if* the path is long
enough.
But that will vary. At 500 miles, usually the dipole will win.
At 1000 miles, usually they will be about even. At 1500 miles the usual
amount
on the S meter is about 2 s units in favor of the vertical. At 4000+
miles,
can be 4 s units.
But of course, this will vary to the quality of the vertical.
In my case, was a full size ground plane, 4 radials, up 36 feet at the

base.
The dipole was at 36 feet. Same height as the base of the GP.
My 40 meter mobile antenna is almost always better than my 36 ft high
dipole
to either of the coasts. I've tested that many times to Fla.
On say a 1500 mile path, usually the vertical will hold the best
overall,
maybe 90 percent of the time, but you will see the shift where they
flip flop
for a short time, and then flip back...
Sometimes the flop will leave them about equal. When back to "normal",
the vertical will be noticably better..2 s units in that 1500 mile
case...The vertical will be better a lot larger percentage of the time,
than
the dipole. I've seen many cases where the dipole never is as loud as
the
vertical, no matter what the shift...But thats usually on the longer
paths.
The longer the path, the larger the vertical advantage. To say VK land,
I've
never seen the vertical less than 3-4 s units better than the dipole at
36 ft.
And I was on about 3 times a week to check at that time. That dipole
would have
to be a whole lot higher than 36 ft to even come close to the ground
plane I ran.
>
> When doing these tests, don't make the mistake of assuming the units
on
> your S-meter are some particular number of dB, unless you have the
> abililty to actually measure them. Any assumption you make could be
WAY off.

True...I make no claim to actual db increase....But I do use switches,
and get
a good A/B comparison...BTW...I think the vertical advantage on long
paths
decreases as you go higher in frequency...Maybe cuz the dipoles are
higher in
wavelength??? Not sure...Seems to be more a lower band, nighttime
thing...The
types of propagation at night vs day may be a factor...MK

> each other.

The dipole feedline and the vertical will interact a great deal unless you take steps to prevent it. That would be to insert one or more "current baluns" (otherwise known as choke baluns and common mode chokes) in the dipole feedline.

Roy Lewallen, W7EL

A 150 foot boom (say 20
elements for example) beam might be perfect for picking up t he lower
angle, which is what I thought you were looking for. The t hree
element beam will bring in higher angle signals as the lobe will
have
a higher angle. A dipole will likely have even a higher, po ssibly a
NVIS angle. .....

Dunno...I've never compared super long yagi's vs short ones, but I
don't
think boom length has a drastic effect on the takeoff angle...The
height above
ground is what really determines that...Same for a dipole...A dipole
has a very
low takeoff angle *if* it's high enough..The various yagi's takeoff
angles *should*
be about the same as a dipole at that same height...Or seems to me,
without
looking into it farther. MK

1681. Groundplane, or something else?

1. Does that efficiency increase come at the cost of bandwidth?

Not sure...Never tested that...But it wouldn't suprise me if it did a
little..

2. Does having the load closer to the base increase the band width, if

all other numbers (coil diameter, coil length, etc) are the same?

Ditto....Not sure....But again, probably a bit...
3. Would getting the loading coil above the "steel" increase my
chances
of making a usable antenna with the bandwidth and efficiency I desire?

Yes, as far as efficiency.

Also using a hat would help a lot, although I know you may not be able
to.
But if you could design a hat, that would help current distribution a
lot.
Take a few turns off the coil too...But the more linear current
distribution
is the main benefit, I think more than any decrease in coil losses....

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

Some people believe that belonging to a local church, temple, mosque or synagogue will get them to Heaven.

Others believe that water baptism, obeying the ten commandments or just being a good person will get them to Heaven.

There are many other beliefs as well, but the good news about God's way to Heaven is found in the Holy Bible.

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins. After Jesus was placed in a tomb He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Bible says, "For the wages of sin is death, but the gift of God is eternal life through Christ Jesus our Lord." (Romans 6:23)

This verse in the Bible says, "For ALL HAVE SINNED, and come short of the glory of God." (Romans 3:23)

This verse says, "But God demonstrates his own love for us in this: While we were still sinners, Christ died for us." (Romans 5:8)

In this passage the Bible clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

Salvation is not a reward but a gift. The Bible says it this way, "For it is by GRACE you have been SAVED, through FAITH and this not from yourselves, it is the GIFT of God." (Ephesians 2:8)

Nothing in the world is more important than your eternal destiny.

The Bible says, "In Him(Jesus) we have redemption through His blood, the forgiveness of sins..." (Ephesians 1:7)

If you have not yet made a decision to be saved, please do so now before it is too late. The reason why it is so important to be saved now is because you do not know exactly when you will die. You may die prematurely in a traffic accident, terrorist attack or some other way before you get another chance to be saved.

The Bible tells us that we will spend eternity in Heaven or a place of eternal torment called Hell. It would be terrible to die and go to Hell when all you have to do is accept Jesus Christ as your personal Lord and Saviour.

Some people that have already made Jesus Christ their Lord and Saviour worry about losing their salvation. The Bible teaches Christians that we can never lose our salvation no matter what happens.

The Bible says it this way, "My dear children, I write this to you so that you will not sin. But if anybody does sin, we have one who speaks to the Father in our defense Jesus Christ, the Righteous One." (1John 2:1)

Yes my friend, Jesus Christ is able to save you and keep you saved.

Please tell your family and friends, thanks!

Have a great day!

Looked in a mirror this morning, Reg? You're doing exactly what you condemn - except that your widely distributed, old wife's, average recommendations are ones you made up all by yourself.

The middle paragraph is the part that's right. But everything else that you wrote either misses that point or flatly contradicts it.

I believe that the TAO is narrower, but, like you said, it is really affected by height and terrain. The range of the TAO of a short beam might be -25 to +25 and a long beam might be -10 to +10 degrees relative to horizontal (assuming maximum height of the antenna).

We are in agreement here. The author wants a small footprint antenna to have a very low TAO, but I think that elevation has more to say than does the antenna design. A three element beam at 20 feet might have a TAO of 14 degrees, but the only thing you can do is point the antenna in the direction you want. I can see pointing the antenna upwards to get a more vertical TAO, but pointing it down won't give you a lower one. Like you say, it takes elevation for that and then it depends on the frequency. If that elevation is 125 feet for 20 meters how can an antenna change it to a lower elevation?

Thanks for the input. I think I have been confused as to what the OP wanted for an answer and no doubt my answers are confusing too. Strangely enough, I am thinking that except for the desire of the OP for a solution, everyone in here is in agreement with the technology.

Mark I never used the word "drastic" however the long boom antenna
will lower the TOA by around a degree. The reader has to determine
the value of this for himself. If one reviews the incomming signals in the
ARRL literature one can see the percentage of signals that come in from
Europe
at 9 thru 13 degrees.These angles by the way are not to be confused with TOA
and explains exactly why a silly db can mean a lot.
It also shows that the long boom aproach has its limits with respect to
lower
TOA and height certainly changes the TOA more in terms of less complexity.
What I am looking for is the latter method but with less emphasis on feed
point height
which will require a deflection method to achieve lower angles. I am sure
that multiple reflectors
and a single director can be manipulated to do this

Dear Ian,

It's early in the morning. I havn't had time and I don't want to take much time thinking about your rather slightly surprising comments.

You have completely misunderstood, gone off at a tangent, about my motives in my very few writings on the subject of baluns.

I have never made recommendations about old-wives tales, whatever you think they are, except, just in effect, to ignore them.

You, apparently, have now (quite mistakenly I venture to add) included yourself amongst them.

Have you any shares in balun manufacturers? After all baluns are the only thing left for old-wives and salesmen to haggle about. Don't bother answering.

In conclusion, unless people can specify, in numerical terms, what is their problem, then there's no hope of sensibly aquiring a balun of any sort. And I have never yet met anybody who has so specified.

I feel guilty at prolonging such a trivial matter. But it's such an early hour of the day. Havn't had breakfast yet!

A very good morning to you Ian.

Reg, G4FGQ

I see what you are asking for. I would definitely want one myself,
but the problem I see with your theory is that the antenna can't
change the earth's effect on electromagnetic waves.

I have never had a beam up 75 feet. I had a TA-33 JR up 35 feet,
about half of the height you recommend. I can't say I had the perfect
TAO, but compared to the dipole and a vertical I was using before I
got it, the beam significantly improved my operating. I was county
hunting at the time (operating with mobiles in each US county) and the
short beam made the difference between not hearing a car and
exchanging 5-9 signal reports. While it wasn't perfect or optimum, it
was an improvement. I guess that is the best we can hope for. A
better antenna for the same space.

I like building mostly wire antennas and I have a few designs in mind
and in the works. There are many to choose from to try. Maybe one of
them will be an improvement.

When it comes to making a contact, I have resigned myself to this one
fact: If there is no propagation between two points, there is no
communications. If there is enough propagation, even the poorest of
stations can communicate.

I wish you the best on your DXing and antennas. I've enjoyed the
topic.

73 for now.

Would the 'ugly balun' be suitable? (wrap 8-10 turns of coax in an 8
inch diameter loop)

That is the standard 1:1 balun I use.

Thanks.

I did see a difference with my two 20 meter dipoles. I had one
stretched, say, due north (0 deg) about 55 feet and another about 45
feet stretched about 75 degrees off. The shield side of both antennas
is where they crossed. I noticed that when I lowered one antenna the
signals seemed stronger from other directions. It didn't make either
unusable though and after Francis hit Florida, I took down the lower
20 to take with me in case I needed it and never put it back up.

In what manner would this vertical be "subpar? "If one were looking for
for a vertical with more radiation in one direction, would this be
something to consider?

Thanks, that was interesting. How well do you think a 40 meter
vertical dipole will fare vs one 36 feet up with radials? The lower
end of the dipole will likely be near the ground.

It would fit on your real estate. If you add three radials you would
have a good ground plane.

I have had in the past the Taylor Radio 4 band vertical and the
Hustler 5 band vertical. I ran both of them with only a 6 foot ground
rod in the ground with no radials. They worked. I doubt that they
worked as well as my dipoles at 65 feet or so, but they did work.

Why do you want the antenna? That may determine how good it is. If
you want a 'money is no object super duper DX antenna', then it won't
be worth the time of day. But if you need an antenna to fit precisely
where that antenna is so you can occasionally rag chew and not spend
any more money for an antenna, it will be perfect.

Egads John, I thought this was a J-Pole for 146 MHz. You are
certainly correct for 30m. The principle still applies but
the fact that it is for 30m may mean the feedpoint impedance
is indeed 23 ohms and the 75 ohm coax solution won't work.
If it is 23 ohms, one would need 34 ohm coax and I don't
have any. :-)

2m signals don't bounce off the ionosphere. It is not clear what
band you are talking about. For sky wave communications on HF, the
polarization doesn't much matter. For ground wave communications,
polarization matters.

Not only will paralleling result in Z0=46 ohms but series'ing
them will result in Z0=186 ohms which will, for non-resonant
antennas, lower the I^2*R losses.

1710. "Compound" SWR question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-01-30 19:12:42 UTC
From: Jaggy Taggy <outhouse@midcoast.com>
Message-ID: <BE229BE1.1247%outhouse@midcoast.com>
Source record: 82749

I am trying to learn more about antennas and transmission lines and am currently reading through the transmission line chapter of a recent ARRL Handbook.

There is a calculated example for a load with a certain SWR connected to a transmission line with certain losses and the author states:

"Because of losses in a transmission line, the measured SWR at the input of the line is less than the SWR measured at the load end of the line."

My first reaction was Oh my God, I am soo proud of my decent SWR at the input of my antenna feedline and in reality I could have a really bad mismatch between the antenna and the transmission line and wouldn't even know about it.

And my second thought was what is happening to the energy, since an SWR gives me an indication of how much power reaches the antenna and how much is either radiated from the feedline or lost as heat and here I have two different SWR in the system, one at the antenna and one for the antenna/feedline system.

I think it can't be that I would loose a whole lot at the antenna (high SWR) but then wouldn't loose all that much for the system since the overall SWR is lower.

Where do I go wrong??

Uwe

> poorly counterpoised groundplane vertical, or something else? Any
> redeeming qualities?

When two radials are 180 degrees apart and elevated, they tend
to cancel the radiation from each other. When you bury one
radial, you ensure that ~half your RF energy is lost. If you
bury that one radial vertically, you do indeed lose half your
signal since you have put half of your dipole underground.
Ground mounted verticals give up approximately half their
power to ground losses. Then they give up approximately another
3 dB to a rotatable dipole. Approximately 10 ohms of the feedpoint
impedance for mobile antennas is ground losses. (Please note that
everything I said is approximate. :-)

Message-ID: <isaLd.11988$2e7.1949@newssvr12.news.prodigy.com>
Source record: 82750

Sheesh, you're right. I was just idly curious about the antenna. I know it isn't the same as 3 elements at 120'. And I did find that it "gets out". But was wondering what results others had, like how is the 80 or 160 version. Those bands may be "pushing it" a bit. But maybe not. It certainly had me grinning, just like when I first built a W5QJR loop years ago and worked JA on 40 CW with 579, loop next to me, ground floor in house...

But thanks for the additional amusement along the way.

Yep, 200 ft. of RG-58 used on 440 MHz will result in an SWR close
to 1:1 whether the antenna is attached or not. :-)

> And my second thought was what is happening to the energy, since an SWR
> gives me an indication of how much power reaches the antenna and how much is

> antenna/feedline system.

The RF can indeed be lost as heat in the transmission line. The
maximum current in a feedline depends upon the SWR. The losses
in the feedline depend upon the current. The maximum voltage
in a feedline depends upon the SWR. The losses in a feedline
depend upon the voltage. At HF, the current losses tend to
dominate.

When I upgraded my antennas (6 and 2 meter) I also upgraded the coax
from 213 to LMR-400-flex due to the lower loss. At 70 cm the 213 is
~6dB of loss and that is rather significant in my estimation,
especially when LMR-400 or 9913 is ~ 3dB. Considering the effort and
dollars that goes into putting up a decent antenna I feel the extra
cost of the coax is worth it.

Not disagreeing with you at all. Just nit-picking about your less than
immaculate grammar!

My only problem with baluns is not understanding the obsession with the
4:1 or 9:1 transformation ratio.

> Sorrrry!

What I said was confusing. Sorry about that. What I meant was
that using twin runs of 93 ohm coax as parallel transmission
lines would result in lower losses than using a single run of
similar 50 ohm coax for non-resonant antennas. That was just an
observation, not an approach that I would recommend. Sorry
for the confusion.

Sure, thanks for the reply.

I have been looking at OCF dipoles and there are some that don't
appear to need a tuner when using a 6:1 balun. I have this dumb
obsession with learning about and working on multiband antennas that
don't need tuners.

I see some of the designs, and I would like to try them. Since the
4:1 is made from material in which I have an abundance, I would like
to know if I can make a 6:1 balun with the same stuff. While I am
thinking about that, if so, I would like to know if there is a rule of
thumb about making baluns like that so I can experiment with various
versions.

One OCF that I looked at showed an acceptable SWR on all bands between
30 and 6 meters with the exception of 17 meters. That's the kind of
thing I like to see and work with.

Roy, W7EL wrote:
"So you`ve improved your transmit effectiveness but haven`t improved your ability to receive."

Exactly, for Roy`s mpre radials under a vertical antenna.

For horizontal antennas, it`s another matter. The horizontal discriminates against vertically polarized signals. Both polarizations result from ionospheric reflection of a signal of either polarization. The most annoying noise usually originates locally and travels to the receibver by a vertically polarized wave, the only polarization propagated by a ground wave.

A horizontal antenna is insensitive to vertically polarized waves, so improving its efficiency possibly improves reception of horizontally polarized waves without a corresponding increase in noise reception.

I worked for years in a system which relayed its broadcast programs by HF radio. This was before satellites, jets, and great recording quality. We also needed immediate relay capability for breaking news. All HF relay systems were horizontally polarized.

Best regards, Richard Harrison, KB5WZI

> And if you hooked it up both ways, it would be a 4:1 BalUn. -kinda-

And, if you solder _everything_ together, they make great radials.

Long story (sort of) short: Back in the early 90's when the U.S.
building and/or fire codes outlawed the material then used as the
outer jackets on RG-62 and the such, a large bank where I was
consulting had to rip out a gazillion furlongs of it from up in
the ceilings of the building. (Probably A Real Good Thing -- if
for no other reason than they always put in "new stuff" for each
new generation of terminal/monitor/display that came along. The
ceilings were overdue for a complete colapse...)

I hauled off as much as I could load into my trunk each day.

By fabricating 1/4 wave lengths of the stuff paralleled in sets of
2, 3, and 4, I built matching sections for various Field Day verticals.
I used the "worst" of it for radials on a 2-element, phased 40M
vertical -- and used 2-pair paralled runs for the phasing section(s)
between the 2 elements.

Used a grid dip meter and receiver to cut the stuff to length.

I did the same thing when I put in the ham shack but I ran 8 runs of
LMR400 cable and also two runs of 8 conductor cable for rotor's.
The outside panel is under the eve of the house and I have another
panel on the wall of the shack.
Tye LMR 400 Ultra Flex is what I used.

I am compelled to add to what the well respected and experienced Richard has said. I have never seen a failure with Andrew products. When supplementing a system some thirty years after installation, I found from measurement that the very long run (about 450 feet) of Heliax put in 30 years earlier was indistinguishable from the new run added along side.

I own no part of the company.

Do it right - do it once.

How many of the eight runs do you use at one time? And I guess the other runs are spares? Did you consider conduit, so you could replace cables if required rather than spare runs?

Thanks, jimbo

It would be subpar because of excess ground losses #1. You only have one radial,
and the antenna is low to the ground.
As far as radiation in one direction, I agree with Roy. It would probably be
about the same in that direction as another "poorly grounded" antenna, except
that in the other directions, it would be even worse. I think in the real world,
you will find it to be hardly directive at all. Or at least enough to be useful
anyway...To be really directive, a vertical system needs multi elements.
IE: phased verticals, bobtail curtains, etc...A bobtail curtain is a mean antenna
on 40m at night. Only the curtains, and the few lucky dogs running yagi's could
beat my elevated ground plane to VK land late at night. A friend of mine across
town ran a bobtail curtain. He could dog my GP most every night. But he's got
three elements compared to my one... MK

I read a thread recently about "Loft Antennas". And I will most likely be facing a similar situation, putting antennas in my attic because of HOA restrictions. I wonder how a mag mount would work installed in an attic with a lead to my shack? How about if I placed a four foot diameter piece of sheet metal on the attic floor and put the mag mount in the center? Any other thoughts would be appreciated.

Thing is....So did my model when using "medium" ground quality.
But I know in the real world, my vertical smoked the dipole on long
haul/low angles. I'm almost positive that the verticals are
"underpowered" when
modeling, unless you bump up the ground quality. Or at least when used
on the low bands at night. To make the model of my dipole vs vertical
actually pan out as in real life, I had to bump up the ground quality
to
"excellent". Even then, it might have been a bit lower than real life.
I'm not sure what to make if this....
I'm not the only one to notice this also.... Talk to W8JI about his
nearly
300 ft dipole vs his verticals on 160m...He always thought the dipole
would be
better. After all, modeling says it should be. But it didn't quite pan
out...
I basically ignore Cecils bad experience, because #1, his vertical
needed more radials,
and he never used it for long haul paths. So of course, the vertical
should
have lost in his case. Heck, even with my vertical, that was a bit
better than his,
I had to get over 1000 miles to start seeing the vertical overtake the
dipole.
Those dipole vs vertical modeling plots are *very* misleading. Or to me
anyway...
Myself, I think the ground qualities applied are in error for some
reason..
They overly stunt the vertical when modeling...Either that, or my
ground here is
really good...My ground quality is pretty good, but it's not *great*,
being I'm
in the city cement jungle of Houston. MK

Should work okay -- I've used a metal serving platter on the floor
with a mag mount dual bander and it hit local repeaters fine.

Could also try your refrigerator, stove, or perhaps a furnace/central
air system in your attic.

Hi OM,

Simple enough to do. But if it doesn't work, shuck the mag-mount;
punch a hole in the sheet metal and attach a real antenna mount. I've
heard the hosannahs sung for thru-glass and mag-mounts, complete with
mumble and jive talk about how they work, but when I can hit my
buddy's 2M repeater 5 Miles away from my basement with a 0.5W HT, it
simply says almost anything can do the job.

A couple of years ago I was keeping a sked with a friend on 10 meters.
The path was about 1800 miles. I mounted a vertical element on the end
of the 3 element beams boom. I wanted to try circular polarization. By
using proper feed line lengths and switches I could switch between
right or left hand circular polarization. The beam had a little more
gain than the single vertical element but the effects were dramatic at
times.

Sometimes right hand was best sometimes left hand was best.

But what turned out to be interesting was when both vertical and
horizontal where in phase and connected together. It lowered overall
signal strength a little but the fading was much less.

At times signals would fade deeply on either vertical or horizontal
polarization. Circular helped a lot but the signal kept changing
between left hand and right hand so you had to keep flipping the
switch.

With both antennas in phase it would receive vertical or horizontal
without changing anything. Very smooth constant signal.

At other times just the beam was better alone.

Transmit appeared to benefit the same. He could hear me with less
fading with the in phase antennas as well. My friend on the other end
only had horizontal polarization. He was going to try a vertical
element too but never got to do it before 10 meters died.

Hi Mark,

Actually, according to the FCC ground conductivity map, you are very
well situated sitting on very good to exceptionally good soil (as you
look towards the Gulf) which is 4 to 16 times better than my own here
in Rain City.

All HF relay systems were horizontally polarized.....

I wonder about the time of day and freq? I'd almost bet many were in
the daytime,
and using fairly high frequencies as far as HF. IE: 31,25,19 m, etc...
Seems the choice was as much a receiving/noise consideration rather
than absolute
signal strength.
I think the choice is much more complex than any theoretical gains seen
in modeling,
ect. In the daytime, I don't think it really matters much. So in that
case, it
would probably make sense to use horizontal to reduce local noise
pickup. That
would improve the receive s/n. As far as transmit strength, probably
not a whole
lot of difference either way.
But at night, it seems to be a different ballgame. I think the
differences in
propagation skew things towards the vertical on the low bands at night.

The farther the path, the better the advantage.
It could be stated that most horizontal wire antennas are lower to the
ground in
terms of wavelength on those bands. This is true. But you still have
cases where
people have tried the high antennas on the low bands, and still see the
verticals
usually win on long paths.
I've never tried it, but any interested could model my 36 ft high
dipole, and then
model my 10 ft center loaded mobile whip, on a ford truck.
I'd almost bet the dipole creams the mobile antenna in the model at low
angles
as far as the gain numbers shown.
But I know in the real world, that mobile beats the 36 ft high dipole
from Houston
to Jacksonville Fla at 2 AM. Yes, even I was surprised the first time I
saw it.
But I tried it over, and over again, and it was not a fluke of nature.
If you could have two 160/80/40 m antennas at 1 wave up, both with the
same exact
gain, IE: one a 1/2 wave vertical with any radials needed to equal the
ground loss
of a horizontal dipole, I'd bet money the vertical would win on long

paths 95% of
the time. It's not just a pure "gain" thing.... I think even verticals
with less gain
will win over the dipoles once the path becomes long enough. Note my
mobile...
I know for a fact from real life, if you are going to run a dipole, and
expect to
equal my 36 ft high ground plane, you better plant that puppy *WAY*
high, or you won't
have a chance. I'm talking over a 1/2 wave up. More like a full wave,
and even then
you might lose, once the path gets to about 4k or so...
BTW, these days in Houston, local noise has just as good a chance being
horizontal
as vertical...Most is powerline noise...So with my vertical, I never
really noticed
any extra noise. The s/n ratio was always better on the vertical, for
long haul.
IE: if the noise comes up 1 s unit, but the desired signal 2 s units,
the noise
is a non factor...Many times I saw no extra noise on the vertical.

I want to build a fat dipole antenna for FM listening for my brother-in-law, who refuses to get an antenna rotator.

He is located with antenna's all around him but not on top of him.

I would of course orient it vertically and use 75 ohm coax from where it is mounted to his tuner.

Does the ARRL Antenna Handbook have directions on building one of these?

I would be using 8 inches as the diameter. Is the math to figure out the length gonna get me - I've been out of college for 30 years and have only done business math since....

Thanks,

Brad

Hi Mark,

You have to think deeper into the ground than the thickness of concrete or asphalt. Unless the project developer scraped off the top 6 feet and dumped it into Galveston Bay for fill, and then backfilled your neighborhood with industrial waste.... RF and your antenna is looking at a BIG foot print below it from your antenna's elevation (probably a greater boon than ground mounted - your experience seems to support this).

This means that when your RF first strikes earth at a DX angle of 5 to 10 degrees, it is a vastly bigger surface than that seen with a ground mount because that ray strikes further away. (About half a mile away, if I did my Trig right.) Instead of illuminating your driveway and street, the elevated vertical is lighting up 100s of acres that averages the ground conductivity over lawns, streets, gardens, homes, lots....

Off hand, I would say the modeler with higher ground settings is validated by your experience and conforms to your environment.

>I would be using 8 inches as the diameter.

Hi Brad,

Well, you sure pegged it down for being Fat. However, this is not particularly useful for just the FM Band. A fat antenna has useful properties as being wide banded (which means you suffer nothing from it being obese), and this would roughly equate to many times as wide as the FM band. (Another)However, receive antennas are not particularly demanding as long as they are high enough to see the antenna that is transmitting. In that regard, and as a rule of thumb, your antenna can see as far in miles as the square root of twice its height in feet (hope that is not too alien from business math). If you figure how high the other (transmitting) antenna is, you can add those two mileages to compute your listening range.

Example: your Fat vertical antenna is 25 feet high (above the ground - on the peak of your roof for instance) and the transmitter antenna is on a hill 250 feet high. That computes to your antenna being able to see about 7 miles and the transmitter being able to see 22 miles. Hence you would be able to hear that program being broadcast from as far as 29 miles out (barring obstructions like mountains in the way).

>
> jimbo
>
Well, it depends on a lot of factors. You have to use lubricant to pull long runs of PVC insulated coax through PVC
conduit, while metal is slicker, and sometimes it will pull without. Metal will provide little additional shielding,
and bending big stuff requires special benders, while PVC can be formed with a heat gun and a lot of care. For
individual runs, you could use this corrugated PVC stuff which has become very popular for pulling fiber optics, but I
have never seen it in real large sizes, and it will need to be held down more if it has a lot of turns.

I ran an OCF in college with a 6:1 air core balun from
Heathkit. It worked well but my transmitter had a
built in adjustable pi-net tuner. What are the dimensions
of the above OCF that you have described? Most OCF's that
I have modeled work just as well with a 4:1 balun as they
do with a 6:1 balun.

Jerry Sevick, W2FMI, describes a 6.25:1 balun in "Building
and Using Baluns and Ununs". It is a 1:1.56 UNUN followed
by a 1:4 BALUN.

EZNEC agrees. With four radials one foot above ground the gain
is -0.53 dBi. With one radial one foot above ground the gain
is -1.62 dBi in the direction of the one radial and - 6 dBi
in the opposite direction.

why are you spending more on coax than you are on an antenna?
why dont you use a base antenna rather than a mobile on a plate?
a VENTENNA would do you just as well and be hidden a WeatherVane antenna
would do the same and have better gain than the dualband mobile
either of these antennas can be found online using a google search and
are both stealthy the neighboors would never know what you have up
if that isnt the issue i would suggest a Comet GP6 or GP9 both are great
antennas
and the performance would be a lot better than the mobile whip

I strongly suggest that you invest in "Reflections II" by Walt Maxwell, W2DU
and sleep with it a few nights.

No offense, but the tone of your questions and comments indicates that you
are working with a number of highly erroneous misconceptions. The sooner you
iron out these kinks, the better you will understand and enjoy your
antennas.

Walt is working on "Reflections III" but it may be this Fall before it
publishes, so the current edition is more than adequate.

However, don't feel bad - the notion of SWR (its causes and effects) is
probably one of the most widely misunderstood concepts in amateur radio.
Walt can help a lot . . .

It is highly instructive to NOT think of a balun as an impedance
transformation device, but rather as a device which has the ability to steer
r-f currents. Thus viewed, a large amount of confusion melts away.

This is the antenna I want to copy before I start experimenting:
http://hamcall.net/6bandmegpole.html

I don't have a lot of information about baluns. What I have is mostly
related to Toroid baluns. I like the air coil idea in spite of the
size requirements. If additional turns or less turns change the balun
ratio, I would be interested to know as I can experiment and try
variations.

Thanks.

Just for information along this line, the N2GG is a form of curtain
antenna. It is only two hanging elements, but apparently a great
little antenna that works better than a dipole.

How does it rate it with that one radial buried in the ground as in
the OP rather than above the ground?

I saw someone who uses a large pizza pan for the radials. The mag
mount sits well on the pan and it was the perfect size for the
radials.

The picture was of the pan on a post outside about roof level, but it
should do as well as the radials inside.

My mobile whip is 5/8 wave with a nub about the size of my pinkie in
diameter and two inches long. If I mounted it on a piece of tin
(covered by shingles) on my roof, the neighbors would never know it
was there even if they looked for it. Chances are that wx won't
bother it in any way either. This antenna has been with me since
April of 1979 and been over 100 miles per hour. It has killed several
birds that didn't expect it when they flew over the car, but it is
still working well to this day. (I used it less than an hour ago.)

the stainless steel whip, especially if painted flat black, will be
extremely difficult to spot if you know to look for it and even harder
if you aren't looking for it.

I don't know why you want FAT. It will give you lower gain. However,
you might consider building a dipole out of 1/2 copper tubing. A
piece of PVC T connector and two elements about 2.4 feet long each can
be connected to the coax, painted (if desired) and mounted inside the
attic or outside if desired.

The formula for a dipole is 234/frequency in Mhz = 1 leg of a dipole
or 1/4 wave length approximately. (Each dipole needs two legs.)

the copper pipe will give plenty of band width and do as well or
better than three inches.

You don't have to be worried about perfect dimensions as you aren't
worried about SWR so the elements I showed you will work very well.

Someone correct me, but don't FM stations transmit both vertical and
horizontal?

I hope this helps.

Mark, NM5K has raised some interesting questions. Time of day and frequewncy?

We operated almost around the clock with both broadcasting and program relay. For broadcast, the schedules are based on propagation predictions and must be published far in advance. The schedule must be followed no matter how propagation actually turns out. The best likely frequency is picked for the path. Also scheduled is something in the next lower frequency band and something in the next higher frequency band. For program relay, you can make unscheduled frequency adjustments at any time it is convenient to do so.

Triple space diversity was the method we mostly used. (3) separate receiving antennas, spaced about 10 wavelengths apart laterally at 40-meters (400 meters) were used to receive all relayed programs. Each antenna fed a multicoupler so that receivers could be connected without interaction.

The three receivers tuned to a particular program (not necessarily the same frequency) had their outputs fed to a single TDR combiner (Crosby or Pioneer). The combiner accepted the best output of the three receivers and rejected the other two. An operator checked the reception regularly to see if the signal could be improved by selection of either the upper or lower sideband, or other means.

The height of the antennas was about 20 meters. High enough for single-hop propagation over the path at midday on the 20-meter band. We had fixed height so it had to serve from 5 MHz to 18 MHz at all hours. For relay, we adjusted frequencies almost 24-hours to pick those frequencies which were working best at the time and might also be transmitting in the next higher and/or lower band during changing conditions For relay we used 3 to 5 KW. For broadcast we used 50 KW and 100 KW. Antennas had about 15 dBd gain on both relay path ends. For broadcast we used 15 dBd gain on the transmitter. The receiver may have had a wet noodle for an antenna. If it was good enough for the jammers it was probably good enough to receive us too.

Mark also wrote:
"I`d bet money the vertical would win on the long paths 95% of the time."

The vertical has its null directly overhead, and it has its maximum radiation at low vertical angles from the horizontal. A hazard for the vertical is low uncorrected soil conductivity beneath the antenna.

Put the horizontal antenna up high and it works with either low conductivity or high conductivity soils. Low height is the hazard for the horizontal antenna if you want DX.

Best regards, Richard Harrison, KB5WZI

Hello everyone!

There's now brand-new steel roof over me and time to put up a vertical. Dont want to spent too much time over that slippery and rather high roof messing with traps, so: planning to put up a fishing pole (7 m long) and coil wire around it. Would like to use rig's autotuner and short run of rg6 cable. Dont mind swr 5 or so. Played with EZNEC and found that 12 m long radiator would present reasonable impedances at 40, 30, 20, 17, 15. But, when my mast is 7m long, should I coil 12 m or more wire around it?? Should I use capasitators at the base of the antenna to to tune out reactances? Or can tuner do that on the other side of coax? Anyone done something similar? Any comments?

Andrus

What does your Autek RF-1 analyser say the resistance and reactance is?

If the reactance is capacitive, lengthen the 1/2 lamba section.

Thee are two things you have to take into account:
1. tuning your radiator to resonance (reactance = 0 on Autek)
2. matching to your feedline.

What does your Autek say?

If the reactance is capacitive, lengthen the 1/2 lambda radiator. If it is
inductive, shorten it.

Now that the antenna resonates, you have to match it. The antenna handbook
details calculating the proper length of 75 ohm coax to transform
impedances from 50 to something else. Your Autek will tell you what the
"something else" is.

Why a J-Pole?

Would it not be easier to simply string a vertical dipole? A J-Pole is
merely an end fed vertical dipole with a tapped shorted 1/4 lambda
matching section.

Message-ID: <pgrLd.4401$bu.1944@fed1read06>
Source record: 82717

From URL:
http://www.astronantennas.com/polarization.html
In the early days of FM radio in the 88-108 MHz spectrum, the radio stations broadcasted horizontal polarization. However, in the 1960's, FM radios became popular in automobiles which used vertical polarized receiving whip antennas. As a result, the FCC modified Part 73 of the rules and regulations to allow FM stations to broadcast RHC or elliptical polarization to improve reception to vertical receiving antennas as long as the horizontal component was dominant.

> http://hamcall.net/6bandmegpole.html

Hi Buck, they don't give exact building information as far
as I can tell. Here's what they say: Inverted V with the
center at 32 ft and ends at 8 ft. Approximately 135 ft
long fed with 100 ft of RG-213.

Why 32 ft with the ends at 8 ft? Because that is the
configuration that gives the advertised values of SWR.
Why 100 ft of RG-213? Because the losses in the coax
results in the advertised values of SWR. If you deviate
from their configuration including having different
ground conditions, you will, no doubt, need an antenna
tuner for some bands. They have probably fine tuned their
configuration so they can make their claims which you
probably will not be able to duplicate. I don't want to
discourage your experimentation - just make a prediction
based on experience.

If you really want an efficient all-eight-HF-band antenna
requiring no tuner, you can find one on my web page at
http://www.qsl.net/w5dxp/notuner.htm
If you don't want to go to the trouble of varying the
length of your feedline, you can at least learn what
you are up against in your quest.

I don't have NEC-4 so I can't bury radials. Perhaps Roy will
do the honors. Incidentally, the above simulation was done
for a 33 ft vertical with 33 ft radials on 40m.

Did you look at your radiation pattern on 15m with that
12m long radiator? TOA = 41 degrees. To get a 5/8
WL vertical on 15m, it shouldn't be that long.

Also coiling the wire may cause a nasty self-resonance
setting your frequency upper limit lower than you want.

thanks, Cecil.

I have looked at that before.

(Not to argue with you, but I considered your feedline switches a
form of tuner, just not conventional ;).

That is definitely a great looking antenna. I am glad you pointed out
the precision needed on the OCF I was looking at. What I am working
towards is a great all-band antenna that can be easily ported and
setup and used without switching (kind of like the T2FD) and no
unique parts required.

I am glad to meet you (and know who you are.) To be honest, I have
spent a lot of time on your site. At one time, I could have answered

many questions about your antenna without looking at it. Your site is the first place I saw the ferrite beads on the feedline for a choke and I have investigated them in depth since then too.

One thing I didn't find about the antenna was the bandwidth of 40/80 meters or an SWR chart for each band. (I realize that you might not be able to do that easily, I'm just stating an observation.)

Also, in addition to the antenna I mentioned to you (It was only one of several OCF's I am looking at), it seems to be common for OCF antennas to use 6:1 baluns. Some do use 4:1 and most, regardless of the balun, require a tuner.

I have several ideas that I am kicking around so being able to easily be able to build an inexpensive balun at different ratios will come in very handy for my experiments.

Before the internet there were books. The best one could hope for was to see a picture of the author on the cover, but now, after all these years, I am still amazed when I find myself in conversation what use to be ... the untouchables. :)

It was great to meet you. Thanks for replying.

Buck.

My apologies to the OP and others.....

I don't know why I said 'lower gain'. (make a note to myself, don't
answer usenet when I should be asleep.)

The fatter dipole will offer a broader bandwidth and a reduced length.
However for the FM broadcast band reception, bandwidth isn't a
problem.

Thanks Roy and Richard. My apologies to you Brad.

I am using a 32 ft gound mounted homebrew vertical with 30 radials of
whatever will fit in a 50 by 50 ft area
I feed it at the base with a 4 to 1 voltage balun and bypass the balun for
use on 40 meters.
swr anywhere from 40 thru 10 meters isnt over 3 to 1.
I feed it with 30 ft or so of good quality rg-8 coax and a little auto tuner
in the shack.

It`s a fact. Fat antennas have more bandwidth, and that is inversely proportional to Q. Teducing antenna Q, by fattening the antenna, reduces the antenna potential by about the same factor.

A twin-lead dipole may be fat enough. These are sold at Radio Shack and other outlets for just a few dollars and can be used to determine if such an approach is satisfactory. You can still build an "improved antenna" if the bought antenna works on site.

reggie wrote:
"I would like to build baluns with non-conventional ratios,---"

"Conventional" may mean a coil balun such as was common for TV reception not so long ago. These were essentially transformers with a two to one turns ratio which provides an impedance ratio of the square, or four to one. This is similar to a center-tapped coil. The TV balun gives a 75-ohm coax connection to a 300-ohm balanced twin-lead connection.

My 1987 efition of the ARRL Handbook shows how to use RF transformers to step up / step down impedance in Chapter 16. Also, ON4UN shows how to match high-impedance to coax on page 6-14 of the 2nd edition of "Low-Band DXing", an ARRL published book.

The HF bandwidth of that antenna *plus* the tuned feeders is 27
MHz, all the way from 3 to 30 MHz with an SWR of less than 2:1
(for the ham bands). I haven't measured the SWR outside of the
ham bands. There's a graphic that shows the SWR=2:1 bandwidth
for 40m to be about 160 kHz for a fixed length of ladder-line.

hi justin
welcome to 6 meters
unfortunatly i dont think just cutting the stinger down will drop the
SWR enough to get to 6 meters that load in the middle would be to big
why dont you just make a 1/4 wave ground plane out of an old 102in whip
and never mind the magmount
also you could build a wire dipole its only between 54-56in on either
side of center and fed with 50 ohm coax
good luck

Hummm. Maybe that explains the large difference I saw between it and
the ground
mount. I know the antenna seemed to really come alive once it's up
about a 1/4
wave. I never was too crazy about ground mount verticals. To me, it's
like
ground mounting a dipole...Makes about the same sense....Of course, the
GP may
not be for everyone...Not really hard to put up, but it's a 68 ft tall
antenna,
the way I had it installed. I took it down a couple of summers ago,
because the
lightning had been so bad. Was paranoid I'd take a hit eventually...It
was
boom-boom every day at that time...It's now resting on the side of the
house..

"Richard, If you got this off Terman and Kraus then Terman and Kraus are a couple of the oldest of old wives."

I can`t blame them because I wrote without consulting them first.

Terman does in fact say about what I said. I haven`t checked with Kraus yet. In his 1955 edition on page 921 Terman writes:
"The second possible way to achieve broad-band characteristics consists in starting with a resonant antenna (as opposed to a rhombic for example), but so proportioning this antenna as to minimize resonance effects. Thus a resonant antenna employing a thin wire is equivalent to a moderately high Q system and so has a relatively narrow frequency band.
However, if the diameter of the antenna is made large, the effective Q is very substantially reduced with resulting increase in bandwidth."

Put the horizontal antenna up high and it works with either low
conductivity or high conductivity soils.

Same for the vertical.

Low height is the h azard for
the horizontal antenna if you want DX.

Yes, but even high, they aren't always the best choice on the low
bands.
In a way, I think the same can apply to the verticals. Low height is a
hazard for those too, unless you have a load of radials...:/ MK

Hello Cecil,
Is it appropriate to apply the above discussion to two random-wires, end-fed (coax) from a 4:1 Balun were one half of the Balun output is directly connected to ground? I would like to experiment using one or more radials (laid on the surface of ground at first, buried if that helps). for this antenna. Electrically, the antenna is about 1/8 wavelength for some frequencies, and as much as 9/5 wavelength for others. The angle of the wires is about 45 degrees elevation. One wire is about 76' and the other 42'long. I use an ATU for this antenna and it has no trouble loading anything, however only 5-15 mhz is reliable for DX. Due to the antenna's location on the property line, I could only apply radials 180 degrees (along its axis) and of course if permanent, would have their ends bonded to the station/service ground, etc.

Thanks for suggestions...

Yep, just like paralleling resistors. I used to run two parallel RG-59 feed lines to my 1/4-wave verticals. It matched the vertical impendence very nicely, and the amplifier's PI network tuning could handle 36-ohm load OK.

As a competent and experienced engineer, it should then be simple for you to answer the following:

What is the gain difference, in dB, between a dipole resonant at 97.5 MHz (the geometric center of the FM band) which is 1 mm diameter and one which is 1 cm diameter? Feel free to assume that the conductor is perfect, or use copper if you prefer.

Also feel free to calculate the antenna Q and "antenna potential", although the question here is about gain.

Hi Roy,

What an unusual demand to throw in the face of someone who agrees with
you: no difference in gain. Richard's quote is merely your ironic
question to Buck's quote (already discounted by Buck).

However, for Brad's interest (and conforming to his original design,
not of 1cM but more like 170mm diamter) the Q for the fatter dipole is
indeed much less (in fact it covers the entire FM band into a 50 Ohm
load between 2:1 VSWR points) where the thin dipole (1mm) is something
less than 6MHz. Bandwidth (and inferentially Q) differential 4:1
which would translate the input V to the tips to something less (at
the same proportion) than that experienced with the thin dipole (which
for a recieve antenna is a strange characteristic to focus upon).

If you were agreeing with me, Richard (Harrison), I apologize. It wasn't apparent to me with my poor language skills. Thanks to Richard (Clark) for effectively applying his superior parsing skills to the problem.

There are only two ways to change the free space gain of an antenna -- change the efficiency, or change the pattern. Those are all the choices you've got. A fat antenna is certainly no less efficient than a skinny one -- in fact, it'll be more efficient. But the difference in this case would be so small as to be unmeasurable. There would be some very slight change in pattern between a fat antenna and a slim one, but again the change would be negligibly small.

Considering only free space performance to remove the additional variable of ground reflection, and assuming that an antenna is essentially 100% efficient, it's impossible to design an antenna that has gain in its best direction which is any less than 2.15 dB below that of a half wave dipole. The lowest possible gain of any efficent antenna is the isotropic, at 0 dBi.

Roy Lewallen, W7EL

If you can get inside the coil housing and short-out some of the windings,
you may have a better radiator.

I'm sorry Jack, I don't understand the question. If the two wires
are equal length and the currents are flowing in opposite physical
directions, the far fields will tend to cancel.

The ladder-line comes off at right angles to the balanced
dipole so common-mode current is minimum and is choked
on the transmitter side of the ladder-line length selector.

Balanced currents don't cause "RF in the shack". If the
currents are unbalanced, RF in the shack is likely with
either coax or balanced line.

Sorry Cecil, I'll be more clear:

I have a random wire antenna, it has one coax-attachment (feedpoint) from which two different length wires start from a 4:1 Balun on a ground rod, up to a Pine tree about 60' in the air. The shorter 42' wire terminates via insulated connector and non-conductive line to the main 76' wire that continues skyward (about a 45 degree angle) until it terminates at an insulator before the support line finally connects it to the high tree limb. Some folks call this a "fan" arrangement.

A Radio Works 4:1 current-type Balun has two output connectors, and both random wires start at one of those connectors. The other connector (normally intended for the other half of a dipole) is shorted to the ground rod the Balun is mounted to. This is a noise-limiting design from an old Fine Tuning "Proceedings" article.

My question is, if I added a long radial (on the ground) from that ground rod, all the way under the sloping antenna wires, would there be any benefit in the transmitting pattern? How about two radials, 180 degrees from each other (one under the antenna, the other 180 degrees away from it)?

I sounds kind of like creating an 1/2 underground dipole, which you and others well explained is a non-starter. But the antenna also has characteristics similar to an inverted-L, and I believe those can benefit from radials. The antenna has been easy to manually tune via an MFJ-962D, and an MFJ-994 ATU makes quick work of any thing I have loaded it with. Could radials improve this "random wire(s)" antenna, or just soak up more power?

Thanks a lot,

Jack

1824. A 1930's two-pole knife switch

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-01 10:40:22 UTC
From: "Airy R.Bean" <Me@privacy.net>
Message-ID: <3694qrF4vhie1U1@individual.net>
Source record: 82663
Cross-posted to: uk.radio.amateur,rec.radio.amateur.antenna

Having recently obtained a 1930's two-pole knife
switch an a porcelain base, I decided to make use of it
in my own shack. Seeming to be of copper, on inspection
it proved to be copper-plated brass. The rivets forming the
hinge on the knives were loose and could not be banged-up
so I drilled them out and replaced with 2BA screws plus
locknuts.

So, now I can earth the G5RV when it is not in use, and
disconnect it from the TX.

It brought up something interesting, and that is,
that one half of the G5RV produced no signal
on RX - perhaps in the recent winds when the
lilac tree blew over (Quod Vide), one of the connections
from the co-ax to the ladder sections has fractured; that
remains for investigation.

This is thin coax which has been installed for about 22 years.

I was intrigued to find that both the braid and the inner conductor
were blackened, despite being on a section of the cable that could
not have had water ingress. Perhaps is time to replace with some
larger diameter coax?

The problem is not '(liquid) water ingress' but diffusion of water molecules from the atmosphere through the cable sheathing.

>Perhaps is time to replace with some larger diameter coax?

The cable sheathing may not be that much thicker than that of the 'thin' coax, and so will not significantly slow the diffusion, and in addition you will have mechanical problems due to the much heavier coax.

Your thin coax probably blackened years ago.

You can try to reduce the effect by covering the cable sheathing with a light coating at regular time-intervals of something water-resistant such as wax furniture spray or WD40 - not as '(liquid) water' is the problem, but that the light fractions of the wax or oil will tend to fill the pores in the sheathing material and so delay the diffusion effect. You could move to the Arctic or a desert of your choice ;-)

If I understand it correctly, I would guess that radials would
help that antenna. Sounds like you are losing half your power
in the ground rod. Two radials are better than one and the more
radials the better.

Thanks Cecil. It probably is a power-sink when xmit. The antenna was originally set up as a receive-only antenna, and you should hear the difference in volume when the grounded side of the Balun is off/on the ground rod. Audible increase (for DX purposes, where a couple of S-units is a lot, hi). I'll try the radials, and disconnect the shorting ground, and see if this improves things a little. I never heard anyone mention making a "vee" dipole antenna (from the ground-up), is that a NVIS?

A balanced-V would not have very much vertically polarized
radiation and thus would probably be an NVIS.

Cecil - I stopped using baluns for dipoles when my neighbor's TV reception was getting killed every time I went on 10 meters. I took out my W2AU balun, and no more problem. Whenever I need to match higher or lower antenna impedances now, I use a 1/4-wave length of the appropriate coax line to get close to the antenna impedance. Works great, seems impervious to the weather, and have never found the unbalanced feedline to balanced antenna (dipoles & full wave loops/quads) was a problem that feeding the coax away from the antenna in a perpendicular fashion wouldn't solve. Also, two parallel RG-59 coax lines feed grounded verticals nicely, and a tuner or the amp pi network can easily do the load match.

==========

A not-very-well-remembered true story.

Shortly after WW2, a British Post Office cable ship was repairing (or
stealing for reparations) a coaxial telephone cable in the North Sea,
somewhere off the Heligoland Bight. It had been manufactured and laid by our
European friends, the Germans, during the war.

The cable was polyethylene plus air insulated. The inner conductor was
insulated by a thick, circular, polyethylene string or rod, slowly
spiralling around it. Plenty of air space. There may not have been an outer
conductor - the return conductor could have been the North Sea water. It's

OK up to a few KHz. But the whole thing was protected by a thick polyethylene sheath in contact with sea water. Polyethylene was a very uncommon material in those days.

(It has always amazed me how much time communications engineers had to spare in experimenting in the middle of a world war. The Russians experimented with future, peacetime, high-voltage DC, single-wire power transmission while the population was dying by the million from murder, starvation and disease. I obtained some of my programs' formulae for calculating the resistance of ground electrodes from a translated Russian book of the time.)

The above-mentioned unbroken cable was laid across the deck of the ship. The cable jointer, not knowing quite what to expect, had his tools around him, including a lighted parafin blow lamp.

The cable jointer, a skilled workman, cut into the sheath with a saw. And immediately there was a hissing noise and a very hot flare of pale flame. Whether the jointer was injured or not is lost in history. (I was either in Hong Kong at that time or was walking the darkened pavements in Hiroshima marvelling at the lighter-coloured shadows cast on the paving slabs by the first of the WMD.*)

It later transpired in the laboratory that when water is under relatively high pressure, such as at the bottom of the North Sea, when in contact with a thick polyethylene membrane it dissasociates into hydrogen and oxygen. The very light element diffuses through leaving heavy oxygen on the outside. Thus, after a few years, the air-space on the inside becomes filled with high pressure hydrogen. If there's any copper on the outside then presumably it becomes blackened by copper oxide.

A tongue-in cheek WARNING - When digging up very old air-spaced coax from soggy soil in your back yard it is advisable to erect no-smoking notices.

(* Actually, the RAF, of which I was a member, had already incinerated more people than both atomic bombs just in one fire storm on one city. Churchill might have been knighted for services rendered. But Air Marshall Bomber Harris was never decorated with a medal or honoured with a statue. He, partially responsible, with 10,000 air-crew plus 100,000 ground staff, took the ashamed blame. After all, there are very few problems in finding 100,000 people to manufacture and operate and transport 5 million people to the gas chambers.)

I'm on South African red wine tonight. It says on the bottle it should be drunk within 12 months of purchase and within two days of opening. I have a corkscrew. No problems!

Help yourself to a program.

Roy, W7EL wrote:
"There are only two ways to change the free space gain of an antenna---change the efficiency , or change the pattern."

I agree. Terman defines "directive gain" and "power gain" which involve the pattern and efficiency of an antenna.

The isotropic antenna is by definition omnidirectional. All others are more directional and thus have gain in their best direction.

The power ratio of a 1/2-wave resonant conductor radiates in its best direction 1.64 times the power per unit area from an isotropic antenna. This is a simple power ratio, not dB. This is from Terman`s Table 23-1 in his 1955 edition.

My original posting in this thread was based on the fact that antenna voltage distribution depends on constructon and frequency. Voltage amplitudes at all points on the sntenna increase when the rms voltage at any point rises.. Radiation and reception from an antenna are a function of antenna voltage. This is unrelated to directive gain.

A higher antenna Q results in higher voltage. The dipole we discussed was resonant. We`ve seen the textbook curves for resonant circuits which pften show impedance versus frequency, and we have tuned lumped and distributed versions. A high Q series resonant circuit has little resistance to limit current at resonance. A high Q parallel resonant circuit has little conductance to limit voltage.
My posting said: "Reducing antenna Q by fattening the antenna, reduces the antenna potential by about the same factor."

A higher Q antenna results in more voltage, more radiation, and more reception. It also has less bandwidth.

I usually read Roy`s postings because they are interesting and I often learn something from them. They are greatly appreciated by me and many others have said they appreciate them too. Some aren`t even EZNEC users, so there is still room for growth.

On the issue of antenna Q, I recall a Yagi design article which advised against large diameter parasitic elements as they would have insufficient Q and not perform properly. That seemed strange to me at the time but maybe there was something to it.

Best regards, Richard Harrison, KB5WZI

For thin (RG58 etc) coax, it is cheap and running it not normally and issue-
so just replace every 12 mths or so (it really does not like the sun!).

For RG213, run inside new hose pipe (B&Q cheap stuff is ideal). Seems to
last 'forever'- well over 10 years without visible deteriotion of the coax,
or measureable change in loss at 430MHz. Not so much about saving money as
hassle lowering masts etc to replace.

Vee antennas (inverted or not) tend to produce quite a lot of vertically
polarised radiation off the ends. Horizontal broadside, of course.

What caused this "disassociation", and where did it happen? Just, I'd expect the hydrogen to bubble off PDQ, assuming this process did occur. Also, diffusion is the movement of something from a high to a low concentration, assuming the mechanism is correct, I wonder how long before the concentration would equalise (after all, the hydrogen around the cable must have been in pretty low concentration.

Was the cable sealed at the ends? If so, what happened the gas (I assume air) already in the cable?

>If there's any copper on the outside then
> presumably it becomes blackened by copper oxide.

How did get to the copper? If the insulation was all polyethylene, how did it sometimes stop the oxygen and not others?

Is Dr Boris around?

Hi Mark,

What Mac is offering is a link to a propagation modeler that was developed for the Voice of America engineers. This sucker is complexityï¿½ and by the trepidation offered in your response, you probably would not like it very much. But that may be an over reaching analysis in the domain of the psyche.

There are plenty of boxes to fill in, plenty of settings to establish, and a host of targets to select. What they describe are your power, your antenna, your path (which presumes you know your audience - literally), their background noise level, the time of day, the height of any ionospheric layer, the sunspot count. From this you get probabilities of S+N/N at the receiver, fluctuation of signal level, even issues of multipath and other interference.

What is the actual payoff is that it also paints a picture of the characteristic of interest either in the form of a chart or on a map. This makes for nice 24 hour MUF forecasts for your intended target (a sub continental sized region on the globe) or actual signal levels, or interference levels (and on and on and on....).

The software also allows you to tailor your antenna's characteristics. I like to describe an impossible design with a 1ï¿½ beam width and beam height to then present me with a map of the world where it hits. This, in a nutshell, pretty quickly dissolves arguments about the value of any particular TOA. Why? Because even with this impossible thin razor's edge of a lobe, when it leaps across the continent it splashes down into a fairly large region. A standard monopole radiation characteristic will illuminate continental wide swaths of the globe with alternating layers of good reception and poor reception like ripples across a spherical metallic sea. The link:
http://www.qsl.net/kb7qhc/propagation/index.htm
offers just such a treatment with 24 forecasts of a standard monopole (one each hour in a day) in an animated GIF loop. It is interesting

to see the sun revolving around Seattle (Galileo had it all wrong as science will prove). Please note the server at qsl.net is quite slow to the point of downloading all 24 images to run the animation.

TV and FM broadcast transmit antenna designs include many using 1/2-wave, resonant dipoles with "fat" radiators -- however they all have published gains based on the standard gain of a dipole (1.64X that of an isotropic radiator). There is no difference in gains between slender and fat radiator designs in the broadcast industry.

Examples on request.

If you'd like something simpler, I highly recommend W6ELProp, a free and very capable propagation program. (Note that's W6EL, not W7EL.) Shel, W6EL, created the DOS program MiniProp and sold it for many years. When time came for the major job of rewriting the program for Windows, Shel did it -- and generously made the program free, as W6ELProp. It doesn't do the fancy graphics of the big government programs, but its predictions are quite good, and it's very easy to use. I've used it and its predecessor MiniProp for a long time.

You can get W6ELProp at http://www.qsl.net/w6elprop/.

Richard Harrison wrote:
> . . .
> A higher Q antenna results in more voltage, more radiation, and more
> reception. It also has less bandwidth.
> . . .

There's a problem here. Let's say we begin with a smallish loop antenna, one small enough so it has essentially equal current around the perimeter. We'll make it using a perfect conductor. Put 100 watts into it; since it has no loss, 100 watts will be radiated, distributed in a dipole-like pattern.

Now reduce the size of the loop. The Q will increase.

You've said that because of the increase in Q, it will have more radiation. My question is, does that greater radiation result from a more directional pattern, or from more power being radiated? If the former, why would the smaller loop have a sharper pattern than the larger one (considering the assumption made about the initial loop size)? If the latter, we've really stumbled onto something here -- more than 100 watts out with 100 watts in. Perpetual motion, here we come!

I would think it would be NVIS. A lazy Vee (horizontal wires) is
directional going from the point through the midpoint between the two
ends.

If it is directional horizontal, it must be directional pointed strait
up.

Dear MK:
You speculated about the performance of some antennas. Performance
includes antenna gain distribution and ionospheric propagation. The
programs that I, and others, mentioned would provide you with meaningful
performance numbers. I thought that you might wish to know the performance
of the antennas you discussed over the paths mentioned (and other paths).
Such knowledge might reduce the uncertainty of the speculations. It is an
engineering sort of thing. Not all are enamored of changes in entropy.

Please disregard my suggestion. It was not matched to your desires.

Adding a single radial under 45 degree random wires did not have a
noticeable effect on 2182 performance under the midday sun. 100 miles was
it's maximum and barely readable (both ways) from the one station I talked
to. Even if I did configure it for NVIS, that would make a totally useless
daytime antenna for MF, with all of it's energy being absorbed. The
Canadian stations certainly do well, being loud and clear from Halifax, St
Johns, Placentia, Labrador, St Anthony, all the way to the Mid-Atlantic. I
guess a vertical or high elevation 1/2 wave dipole are the only solutions
for daytime success there. Maybe a job for the super-Isotron, hi, hi. But
seriously, I might try a much longer wire, something close to 1/2 wave, with
a feedpoint-choke but no Balun.

Why does everybody insist on OVER-COMPLICATING this simple problem?

The Q of a resonant 1/2-wave dipole is given by -

Q = Omega * L / 2 / R

Where L is the end-to-end wire inductance and R is the radiation resistance
of about 71 ohms.

Just the same 'formula', in fact, as any other tuned circuit or transmission
line. Resonant rise in voltage and current, and bandwidth, etc., all
follow.

It's so simple it doesn't occur to Terman and other 'beings' to mention it.

Sorry, I left out a couple of words. Should have been
"A balanced-V would not have very much vertically polarized
low angle radiation and thus would probably be an NVIS."

>
> Please disregard my suggestion. It was not matched to your
desires.

If you say so...I just wanted to know what the program does.. I don't
have a lot
of room on my drive, and when they start talking about "install"
programs, ect,
it makes me think the program is pretty large. I don't think I really
"speculated"
about the antennas. I just described my results with them. I did
speculate as to
why I have to bump up the ground qualities in the modeling programs to
match my
real life results. But I think Richards theory about the elevated
performance
was about as good as any. I may try some of the programs later. I need
to get a
new drive..My present one is crammed full..I have to shuffle junk
around to make
room for big programs. My flight sim, and 1000's of old pictures I
store, hog all
my room...Not to mention a zillion zip files...I'm like a packrat when
it comes
to data....:/ Time for a new big drive...I rebuilt my puter last
summer, but
not the drive yet...I'm still on a puny 6.8 g. I need about a 100 g...
BTW...I'm not sure why my type is constantly messed up as far as the
lines, etc.

I'm using google, and I *hate* their post entry window...It doesn't
autowrap like
I'm used to, and I never know how to make it look normal...If you try
to let it
autowrap the lines, it just types off to the right forever...I never
had this
problem with the old google...If I try to match the width of the
previous post,
it still usually ends up all goofed up...Don't worry...It's not an
excess of wine
causing the problem. :/
MK

1861. Re: Fat dipole for FM

Source record: 82600

"Reg Edwards" wrote
> Just the same 'formula', in fact, as any other tuned circuit or
> transmission line. Resonant rise in voltage and current,
> and bandwidth, etc., all follow.

The impedance bandwidth of a fat dipole can be so large that an acceptable input match is possible at frequencies where the dipole is no longer very near a resonant 1/2 wavelength. In those cases and at a constant input power, there is a redistribution of the current in the radiators, resulting in a relatively modest change in the peak gain of the radiation pattern.

It is true that the Q of a fat radiator is less than a thin one, but that in itself does not produce a change in gain. A gain change results from a change in the radiation pattern of the antenna -- which is related only to the length of the dipole elements with respect to the operating frequency; independent of Q.

For example, a "short" dipole (fat or thin) has a gain of 1.50X and a 3dB beamwidth of ~90ï¿½. A standard 1/2-wave dipole (fat or thin) has a gain of 1.64X and a 3dB beamwidth of ~78ï¿½ [Kraus, 3rd Ed, Table 6-2].

Another example is that of the vertical radiators used in MW AM broadcasting. There is no term for Q in the equations for their radiation patterns. For a given set of installation conditions, a thin tower produces the same elevation pattern/peak gain at the carrier frequency as a fat one.

Water dissociates naturally to a small extent. Think of how the pH
scale is derived.

>Just, I'd expect

It all sounds a bit like Maxwell's 'demons' but my half-educated guess
is that the polyethylene was acting as a semi-permeable membrane,
allowing only the much smaller hydrogen atoms (ions?) to pass through
under the action of the pressure differential.

I thought the pH scale came from "per Hydronium"- H30+ ?

If the 'extra' H came from the water, then there would also be OH- to
neutralise it.

Semi-permeable membranes feature in osmosis, rather than diffusion (although I have heard osmosis related to diffusion in via the concept of the solvent diffusing).

> allowing only the much smaller hydrogen atoms (ions?) to pass through

As I recall, a hydrogen ion doesn't stay 'free' for long.

Long time since I did Chemistry, is Dr Boris not about?

1865. FAST AND EASY LEGAL MONEY

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-02 16:14:53 UTC
From: mvagustas <george512tr@prodigy.net>
Message-ID: <1107360893.211415.111880@l41g2000cwc.googlegroups.com>
Source record: 82604

ARE YOU IN NEED OF CASH? DON'T GO AND STEAL IT. TRY THIS. THIS REALLY CAN MAKE YOU EASY MONEY!! IT WORKS!!! BUT YOU HAVE TO FOLLOW THE LETTER FOR IT TO WORK!!!! THIS IS NOT A PYRAMID SCAM!! YOU TOO CAN BE RICH!!!!!
A little while back, I was browsing through newsgroup, just like you are now and came across an article similar to this that said you could
make thousands dollars within weeks with only an initial investment of
$6.00! So I thought, "Yeah, right, this must be a scam", but like most
of us, I was curious, so I kept reading. Anyway, it said that you send
$1.00 to each of the 6 names and address stated in the article. You then place your own name and address in the bottom of the list at #6,

and post the article in at least 200 newsgroups. (There are ¬thousands)
No catch, that was it. So after thinking it over, and talking to few people first, I thought about trying it. I figured what have I got to

lose except 6 stamps and $6.00, right? Like most of us I was a little

skeptical and a little worried about the legal aspects of it, so I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal!
Then I invested the measly $6.00. Well GUESS WHAT? Within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. In my first week, I made

about $30. By the end second week I had made a total over $425! In the
third week I had over $1,500 and it's still growing. This is now my fourth week and I have made a total of just over $7,450 and it's still
coming in rapidly. It's certainly worth $6.00, and 6 stamps, I have spent more than that on the lottery!! Let me tell you how this works and most importantly, why it works? Also, make sure you print a copy of this article NOW, so you can get the information off of it, as you need it.
STEP 1: Get 6 separate pieces of paper and write the following on each
piece of paper "PLEASE PUT ME ON YOUR MAILING LIST", your name and mailing address, and your e-mail address, so I can send you an e-mail

with all the newsgroup and newsletter that I posted with your information included. Once I have your name and mailing address, I will post your information to all newsgroup and newsletter all over the
world. You have to do your part too of course. You will need to post the information in this letter including your information to at least

200 or more newsgroup or newsletter all over the world. If you do everything correctly, you will be rich in no time. GUARANTEED!!
Now get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope to prevent thievery. Next, place one paper in each stating the above phrase, your
name and address, and a $1.00 bill. What you are doing is creating a service by this.
THIS IS ABSOLUTELY LEGAL! Mail the 6 envelopes to the following addresses:
1. Hue Le, 581 Independence Drive, San Jose, CA 95111
2. Brandon Butler, 25 Clark Park Rd., Hooks, TX 75561
3. John Huynh, 491 Posada Way, #14, Chico, CA 95973
4. Cheran Shelton, 1184 Wilorraine Place, Rialto, CA 92376
5. John Green, 125 Virginia St, Brighton, IL 62012
6. George Argyris, Woodford Lane Apt. 660B, Yardley, PA 19067
STEP 2: Now take the #1 name off the list that you see above, move the
other names up (6 becomes 5, 5 becomes 4, etc) and add YOUR name as number 6 on the list.
STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups, message board. (I think there are close to 24,000
groups) All you need is 200, but remember, the more you post, the more
money you make!
DIRECTIONS HOW TO POST TO NEWSGROUPS, MESSAGE BOARD
You do not need to re-type this entire letter to do your own posting.

Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit
menu. This will copy the entire letter into the computer memory. Step

2) Open a blank 'notepad' file and place your cursor at the top of the
blank page. From the 'edit' menu select 'paste'. This will paste a copy
of the letter into notepad so that you can add your name to the list.

Step 3) save your new notepad file as a .txt file. If you want to do your postings in different sittings, you'll always have this file to go
back to.

Step 4: Use Netscape or Internet explorer and try searching for various
newsgroups (on-line forums, message boards, chat sites, discussions.)

Just example you log on any search engine like Yahoo.com, go¬ogle.com,

altavista.com, excite.com then you search with this subject? Millionaire message board, money-making message board, employment message board, money-making discussions, money making forum, and business message board? Etc. You will find thousand & thousand messag
board. Click one by one then you will find the option post a new message.
Step 5: Visit these messages boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that

everyone sees as they scroll through the list of postings in a particular group, click the post message button. You're done with your
first one! Congratulations? THAT'S IT! All you have to do is jump to different newsgroups and post away, after you get the hang of it, and

it will take about 30 seconds for each newsgroup!
REMEMBER, THE MORE NEWSGROUPS OR MESSAGE BOARD YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200. That's it!
You will begin receiving money from around the world within days! You

may can rent a P.O. Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use,

as long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT. **
Now the WHY part: Out of 200 postings, say I receive only 5 replies (a
very low example). So I made $5.00 with my name at #6 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at #5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at #4 and only 5 replies each, I will bring in an additional $125.00! Now, those 125 persons turn ¬around and post the MINIMUM 200 with my name at #3 and only receive 5

r¬eplies each, I will make an additional $625.00! OK, now here is the¬ fun part, each of those 625 persons post a MINIMUM 200 letters with my¬ name at #2 and they only receive 5 replies, that just made me

$3,125.00¬!!!
Those 3,125 persons will all deliver this message to 200 newsgroups with my name at #1 and if still 5 persons per 200 newsgroups react I will receive $15,625.00! With an original investment of only $6.00!

AMAZING! When your name is no longer on the list, you just take latest posting in the newsgroups, and send out another $6.00 to names on the list, putting your name at number 6 again. And start posting again. The thing to remember is, do you realize that thousands of peopl¬e all over the world are joining the Internet and reading these article¬s everyday, JUST LIKE YOU are now!! So can you afford $6?? See

if it rea¬lly works?? I think so. PLAY FAIRLY AND HONESTLY AND THIS WILL WORK FOR ¬YOU TOO.
BEST WISHES TO YOUR FINANCIAL FUTURE.
If you are not serious about this Easy Making Money Strategy, please disregard this message. This Easy Making Money Strategy is primary for
those who interested in changing their financial life style.
Remember to INCLUDE your e-mail address in the envelope, so I can e-mail you a confirmation letter with all the newsletter and newsgroup
that I posted with your information on it. This is very important!!
I'm an honest businessman, and I do what I said.

pH is defined as the negative of the logarithm of the hydrogen ion
concentration.

In pure water the product of [H+][OH-] is very close to 10exp-14,
where square brackets indicate concentrations.

Hence in pure water pH = 7 because the concetrations of the two
species are equal.

An acid solution, where [H+] is greater than that in water, has [H+]<7

There is a more exact definition involving hydrogen ion activity.

Reg, G4FGQ wrote:
"Its so simple it doesn`t occur to Terman and other "beings" to mention it."

Well, Ed Laport had experience with many high-powered transmitters, so it occurred to him to mention antenna Q in "Radio Antenna Engineering".

Ed assumes power in a dipole is all radiated and none is used to heat the dipole. Radiation resistance of his horizontal dipole is a function of its height above ground.

To calculate the Q of the antenna, he first calculates a factor "m" which is the ratio of the attenuated voltage 180-degrees from the generator on an infinite line to the generated voltage:
m = Zo-radiation resistance / Z0+radiation resistance

Then: Q = 1+m / 1-m

Radiation resistance = 276 log l/rho

where l is the total length of the dipole, and rho is the radius of the conductor in the same units.

Laport is interested in antenna Q to make sure the antenna won`t plume at maximum voltage.
Ed picks a wire size and computes maximum voltage at the antenna tips to make sure that under assumed conditions the voltage is below the corona firing potential. The calculation is on page 241 of "Radio Antenna Engineering".
A trial wire size has a radius of 0.102 inch.

m ccomputes as 0.84

Q computes as 11.4

Balanced dipole feedpoint volts are picked as 690 rms from the unmodulated applied power.
Volts at the ends of the dipole are:
QV/2=3950 volts as rounded.

Corona is initiated on peaks and a further safety factor is added to avoid pluming, but that`s the way a wire size might be checked.

Best regards, Richard Harrison, KB5WZI

1871. Extending Icom AH-4 tuner control cable

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-02 20:09:14 UTC
From: Jon KB1HTW <kb1htw!@!arrl.net>
Message-ID: <ctrc1h$21f$1@newslocal.mitre.org>
Source record: 82610

I need to extend the control cable for my AH-4 tuner. I have lots of Cat 5 Ethernet cable. The four leads to the tuner are Key, Start, +13.8Vdc, and Ground. I initially hooked up each to each of the four pairs in the Ethernet cable (i.e., Key to Blue/Blue-White). My thinking was parallel each pair so I have less current loss, but I think I blew the capacitance out of the water and the Key/Start pulses are getting smeared along the 100+ foot run.

What's the best way to wire things up so to the twisted pairs so any RFI gets nulled out? Ground to each of the 4 White leads, and Key to say Blue, Start to Green, and +13.8V to Orange? That way each twisted pair would have a "signal" and ground. Or I could use the Brown for Ground, and connect the AH-4 factory cable's shield to the four white leads. Which is the preferred route for minimizing RFI or cable capacitance affecting the Start/Key pulse signals?

How FAT would an FM broadcast dipole have to be to lose one db gain?

approximately

Hi Jon,

Use RS-422 components to translate voltage signals into current
signals, and then back (at the other end) to voltage signals. If you
have surplus twisted pairs, then this will give you the
transmission/length requirements.

Thanks for the info, but I don't think it'll work.

From http://home.comcast.net/~hamlakemn/ah4/ah4.htm (great site for AH-4 info, by the way!)

"The AH-4 uses 12 volt inverted logic and an "open collector" transistor to ground to perform signaling. The radio provides 13.8 volts to the tuner. It also provides a START line that is pulled up to 13.8 volts inside the radio. The radio pulls the START line to ground to assert the signal (start the tuning operation). Similarly, the AH-4 pulls the KEY line to 5 volts through a 22 kohm resistor/diode combination. The radio also pulls this line to 13.8 volts through a resistor. The AH-4 pulls this line to ground to assert the signal (indicate tuning status to the radio.)."

I think it may be more effort than it's worth. Plus, I'm not sure if what I described as the "problem" is really the cause - I just think it was the most likely candidate. I guess I need to check the end of the cable and see if I'm getting better than 12V at the tuner. The author of that website says he's been able to control the tuner using 18 gauge rotor cable up to 60 meters away. My Cat 5 Ethernet cable is probably 24 or 26 gauge solid core - that's why I paralleled the leads. Another possible cause why the tuner can't tune any band is that my temporary ground is probably pretty poor. The tuner's on the roof, feeding a long wire - 14 AWG copperweld, ~73' I just tied the RF ground terminal on the tuner to an old 10 AWG aluminum lightning ground wire that goes down to the electrical service entrance of my house. The ground there is a cold water pipe augmented with an 8' length of 1/2" copper pipe driven 6' into sandy/rocky ground.

Since the AH-4 is supposedly capable of driving a dipole - with the tuner at the center, I think I'll try stringing up another wire as a counterpoise. Only I don't have 150' linear feet of space on my property, so the dipole will end up being a sort of a "J-pole" being fed at the center...

Good thing is that I live on a harbor in Massachusetts, so as soon as the weather's better (like May? ;-( ), I should be able do drive some ground rods next to the seawall, where they'll be in saltwater-saturated sand. Hopefully they'll last a few years... I'm itching to get my IC-706Mk2G up and running HF - 2m/70cm works fine...

Dipoles consisting of radiators of any practical diameter all will have the same gain if they have the same electrical length at the operating frequency. "Q" has nothing to do with it.

RF

Thanks for the overload of info guys. I may have resolved his issue by purchasing a Marantz ST-17 tuner, which has provision for two antennas. The ST-2 that he has is fine for all stations he listens to except one. I'll have him get the Radio Shack Yagi abd some good coax and aim it for best reception on that station.

However, I need to make a good omnidirectional antenna to go in my attic. I did not get an answer on if the ARRL handbook has the directions for makinng the fat dipole.

I live outside of Atlanta, GA (hilly) and cannot have an outside antenna, and have very little room horizonally in attic - a directional is out, but do have an area for a tal vertical antenna.
What would be your recommendations?

What suggestions

I am very sure that QRZ.com is very much aware that they must not charge
your credit card until shipment has taken place. The fact that they did
tells me that you need to report to them that nothing has been received and
ask them to trace the shipment. They are just too reputable, a break down
in the shipping path has occured.

Hello George, don't worry, you and the others who pointed out my misconceptions are not offending me, they are indeed helping.

I started to read the article you recommended, or at least a version of it available on the ARRL website.

The difficulties I encounter are partially (you mentioned it and Maxwell mentions this problem in his 'Reflections' as well) because of the widespread misconceptions about transmission line behavior where everybody has an opinion, but it seems many of them are wrong. So one has to find trustworthy sources.

Also, and maybe you know of a source for this, as I gain theoretical insights I like to strengthen my understanding through measurements and experiments, a "lab companion book" would be great.

Other than that I will shut up for a while and read.

Best regards from Maine

1887. How to restore relays of Antenna tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-03 05:14:43 UTC
From: Andrey <a8421@intergate.bc.ca>
Message-ID: <1103cq0hp75qp67@corp.supernews.com>
Source record: 82476

Hello All,

I am dealing with a bunch of relays that have burnt out contacts: Mechanics works fine but contacts measure 3 - 15 Ohms between them instead of zero. I opened several - the contact pads turned dark gray, almost black. It is not coal, still looks like metal surface. The dark surface is very thin, several passes of sandpaper clean it and relay works fine after that.

I wonder if there is a way to clean the contacts without opening relays (the relays are sealed, the only way to open it to cut the body apart.)

Appreciate any wisdom

Andrey

PS: the relays are used to switch RF power at 2 - 30 MHz

1888. Reflector Length??

Then, the next step is to think about why having less inductance and more capacitance should reduce the gain.

Does it cause the pattern to change?
Does it reduce the efficiency?

Those are the only ways to change the gain.

You can trust the _ARRL Antenna Book_ and Walt Maxwell's _Reflections_(*). There are many good textbooks on the topic, but most get too involved for a beginner(**). You're wise to be leery of sources other than the _Antenna Book_ and _Reflections_, or real textbooks. And web pages should undergo even more critical scrutiny. I see some pretty bad misconceptions popping up in the works of some of the most prolific and, among the amateur community most respected, authors.

(*) No work is perfect. But I know both Walt, and Dean Straw, the _Antenna Book_ editor, personally, and both know the topic very well. At least as important is that both are absolutely committed to conveying accurate information, and do their very best to verify the accuracy of their work and correct any errors which are found.

(**) One you might consider is _Transmission Lines, Antennas, and Wave Guides_, by King, Mimno, and Wing. It's well written, and a paperback edition was printed which you can often find at a reasonably low price. The paperback edition is by Dover, published in 1965.

I would say, Use 4nec2 to let it automatically determine the reflector length and/or spacing for optimal F/B ratio, or send me your EzNec, NecWin+, *.ant data or whatever modeler you are using, and I'll let you know the spacing and/or length.

Arie.

p.s. excuses for the new thread, because somehow I am not able to reply any more on an existing posting because I get below message:

"Unable to retrieve message 1107413944.984889.145320@f14g2000cwb.googlegroups.com"

Anybode having a suggestion to overcome this or how to get more detailed error info ?

thanks bob, for the reply, but first thing i did was to goto radioshack,
and the stuff there, that you pointed out is all cheep thin guage, and
material that will rust solid after the coating wears off

anybody know a place where they sell some good commercial quality
wall mounting antenna brackets??

thanks to all

1897. Re: How to restore relays of Antenna tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-03 14:10:59 UTC
From: John Passaneau <jxp16@psu.edu>
Message-ID: <cttbdi$kj4$1@f04n12.cac.psu.edu>
Source record: 82486

Hi all:
Nope the sonic cleaner uses a cleaning fluid and will not work in this case.
What your doing is the only way to clean the relay contacts. Of course the
real question is why the relays are corroding/burning in the first place. If
this is a auto tuner the first thing I would do is not tune with any more
power than is necessary to make the tuner work. After it finds tune then
raise the power up to the normal level. And I'd make sure I was not running
any more power than its rated for.

Haven't ever modeled this, but do have a Traffie HexBeam. I recall that Mike Traffie told me the 20 meter element driven element was resonant BELOW the bottom of the 20 meter band and that was necessary because of interaction with the other bands. The F/B was good at the bottom of the CW band, but deteriorated as I went up the band, to the point of being effectively bi-directional high in the SSB portion of the band.

<kelly@dvol.com> wrote in message news:1107413944.984889.145320@f14g2000cwb.googlegroups.com...
I'm diddling with the design of a homebrewed 20M hexagonal wire beam a la the Traffie Hexbeam. I have the driven element resonated at 14.150&#65533; in the modeler. Now I have to add the reflector to the model. The question is how much longer should the refelector be vs. the overall length of the driven element in terms of percenatge/scale factor. I'm much more interested in F/B performance than I am in forward gain. Does anybody who has been there have suggestions for a starting point??

1900. Icom AH-4 tuner and IC-706Mk2G radio

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-03 14:58:31 UTC
From: Jon KB1HTW <kb1htw!@!arrl.net>
Message-ID: <ctte75$4rm$1@newslocal.mitre.org>
Source record: 82489

More info, Richard:

I climbed up on my roof last night (from my 3rd floor balcony - always an adventure!) with a flashlight to check my RF ground - sure enough the old cable had a splice that was broken in one place (that I could find in the dark). So I fixed that. I also verified that the internal fuse of my radio (IC-706) wasn't blown (the tuner connector on the back of the radio still put out +13.8Vdc.

When I plugged everything back in, I figured I'd at least be able to tune at least a couple of the bands, but I was met with - nothing. Pressing the Tune button on the radio for two seconds would do absolutely nothing - no changing mode to CW and keying for transmit, not even a short beep saying the tuner couldn't tune the long wire. Just dead.

By then my wife was dragging me out for dinner, and it was too late after for any troubleshooting. And this weekend, I'll be out of town, so I won't be able to do any serious troubleshooting during daylight hours for another week and a half.

Man, this is frustrating...

Brad wrote:
"What would be your recommendations?"
Brad also wrote:
"---but do have an area for a tall vertical antenna."

There are often obstructions in an otherwise line-of-sight path. Antenna gain is usually not enough to overcome an obstructed path. Antenna height can overcome the obstruction.

Flagpoles are usually acceptable where antennas are banned. In Terman`s 1955 edition of "Electronis and Radio Engineering" on page 902 are found "Flagpole Antennas". These are balanced vertical dipoles, transformed to a coax feed through the bottom of the dipole.

If the flagpole is tall enough, you receive FM broadcasts.

Q = f/BW means your dipoe needs a Q of less than 4.8 to span 88 MHz to 108 MHz. The antenna would center upon 97.5 MHz, the geometric mean or center of the band.

Such a bandwidth is likely impractical. You can settle for less or center the response on the part of the band you would most use.

Multiply the lowest frequency of high interest by the highest frequency of high interest and take the square root of the product to find the frequency the dipole should be cut for. The fatter the dipole is, the lower its Q will be, and the more even its frequency response will be. You can probably do quite well with uneven response in your antenna is high enough.

Best regards, Richard Harrison, KB5WZI

Hi Kelly,

5% larger. However, its presence will change the resonance of the
driven element and you will have to approach the solution iteratively.

>> info, by the way!)

Hi Jon,

I consulted the page you offered and given the timing diagrams I would
suggest there are no issues of risetime on leading edges of the logic.
The microprocessor appears to be a state machine looking at levels,
not edges. Anyway, the timings are extremely long in comparison to
any edge issues at these scales. Even with a mile of wire, the timing
is too simple to be upset by slope.

You should have (or now do) designed this and assembled it on the
bench for testing in a warm place (for your sake). Replace the cable
so there are NO splices anywhere (if you found one broken, that is

pilot error).

As for the size of wire. This will never be a problem unless you are running in the 40s of gauge. You MUST however meet the peak current demand. This is for the benefit of the 22 relays. You must confirm the average current demand meets spec too for the benefit of the control circuitry.

Skip the attention being placed on the ground lead down. As long as it is long (and on the roof of a three floor home, length is sufficient) it hardly matters, RF-wise, what it ties to. The only point about it going to ground is for the sake of lightning protection (which seems a matter of luck anyway in this configuration).

I see no discussion of choking either the transmission line nor the control lines on this page. This is poor coverage (or I simply scanned it too fast). This may/may not change your situation, but using them is standard procedure.

Get an O'scope and tie it to the control lines and confirm the timing diagrams illustrated at the link offered. If you have no O'scope, then patch a meter across the lines and at least confirm a twitch of the needle. This won't prove much - unless there is no twitch. The timing suggests this would be long enough to overcome the ballistics of needle mass. If you have a digital VOM, and it offers AC Peak hold reading, this should resolve at least one change of state - it will not distinguish between the fail indication timing waveform and normal operation illustrated at the link however.

If you have the bench talent, you could assemble a simple pulse stretcher from ICs to aid in this troubleshooting. If you are very talented, you could assemble ICs to stretch, clock, gate, and resolve the fail indication waveform. An O'scope is far simpler and by far the surest method.

Source record: 82499

Well, I found a reference to a 10-40 meter flagpole antenna for HOAs that don't like antennas. But they all require radials as long as the vertical height of the antenna, and my minuscule lot just won't be large enough for radials of any significant size. Is there any other option for a vertical antenna for 10-40 meters that doesn't require radials?

In another location, I used a random length dipole under the eves of the house with a Johnson Matchbox tuner with good results. And maybe, I can do the same with a random length dipole in the attic, but the flagpole is an intriguing option. And I was always concerned about the radiation in the house from the antenna and from the ladder line lead. In fact, the irrigation solenoid valves used to open when I transmitted.

Source record: 82500

thanks again for your help bob , not to sound ungreatful

but you'd think this was the easy part of gettng my antenna mounted :)

the new link you mentioned has 2 problems

their brackets are still steal, they will rust, i guess i should have
said i need the brackets to be either aluminum or stainless

any chance you know of a place that has those my usual places don't
carry them

the other bad thing about that site wich btw i tried, is that it has
a ton of dead links on it, and i contacted them to inform them ,and
didn't seem like they cared so didn't strike me as reputable

but i am greatful ---anyone out there know of a place that sells them?

thanks

>carry them

One possible option is to check around at marine-supply companies.
They seem to have quite a few different stainless-steel antenna
mounting brackets of one sort or another. Rail-mount brackets seem to
be the most common, but stick-out-from-a-wall mast brackets are also
available.

http://www.naval.com/flanges/mast-mount-1.5/
http://www.busse-yachtshop.de/dae_antennenhalter.html

"Make it out of stainless, call it marine-grade, and multiply the
price by 5" seems to be the usual approach.

Well I may be wrong here but my understanding is the wires on the ground are a counterpoise and need not be tuned. As they are coupling to the earth. But it may take numerous wires for the counterpoise. Ground conductivity enters into this as well.

Radials on an elevated antenna on the other hand should be tuned. Just four radials on an elevated antenna will do well.

I had a ground mounted vertical and just sprinkled lots of wires thither and yon as best I could to fit in the lot and the antenna tuned fine.

Try it and see the results.

You could try a half wave vertical -- no radials required but now you have an impedance mathing problem.

Some Cushcraft antennas use a half wave end fed scheme, the black box at the feed point is matching unit.

Jim:

I suggest that you do not get carried away with not having room for "full length" radials. I've read some interesting research (I will find the references if you are interested) on this. It appears that radials as short as 0.1 wavelength are quite effective. Are longer ones better. Yes. It is also better to be transmitting in the middle of the ocean.:) It is better to be young, rich, and handsome, too.

Seriously, lay down whatever radial pattern you can. The more the better, the longer the better, but you will surprised how quickly (in both cases) it becomes a matter of quickly diminishing returns.

A friend of mine lives in a restricted community in Southern Cal. He got permission to put up a flag pole, so he and (I was visiting at the time) went out on a Sunday afternoon when everyone could see us and set-up his flagpole, raised the U.S. Flag, etc. Then, about 3 a.m. we went back out and buried 4 radials and a coax feedline. There are not enough radials and they are too short. However, he has no problem working the entire Pacific Rim with 100w.

I live in the sticks, so I can put up whatever I please.
But it seems to me a metal roof with a Fluidmotion SmallIR with a flag on
the roof would ROCK from 20 on up.
Of course folks who wanted just a flag have been screwed by homeowner's
associations.
OTOH a nice copper gutter can get the job done.
Or just build a kick-ass mobile rig.

BTW
Why do people even get involved with such BS, anyway?
I didn't make you live there.

One last suggextion -- a Google search for "Rohn wall brackets" brings
up a number of sellers -- the brackets are made of galvanized steel,
but it's the same stuff Rohn towers are made of, and I'm not aware of
any rust problems on their towers.

Hi all,

I have a 1/4 wave vertical on 440, from this a direct connect to my 440 preamp, which as a 50 ohm input and output, then a direct connect to a receiver which has 2000 ohms impedance.

Does it make a different if the receiver input is not exactly matched? Should I try to set up the 50ohm to 2000 or step down the 2000 to 50 ohm?

Jon,

get your control cable choked before trying anything else. You can use a
pair of split core ferrite beads. Put them close to the cable's ends to stop
induced RF from getting into the circuits.706MKIIG is sensitive to that.
Better then, get a larger core diameter and make as many turns as you can
fit. Same thing applies when you want to extend the control's head cable.
A better option would be to use a shielded cable, not TP. What happens is
that your cable works as an antenna, feding RF back into the radio which may
cause unpredictable results. In case of the remote control head this simply
shuts the radio down when trying to key it.
But you still should be able to get away with your existing TP cable if you
chop the RF off at both ends.

Hi Jimbo,

All the responses you have received so far are good, But one other
possibility is to install a fiberglass flag pole with a diameter big
enough to accomodate and R-7 or similar no ground vertical. A freind
here did that and it worked quite well.

Hello All

I am beginner in RF
I may ask about some silly question and please pardon me
May I know what actually the unit of dbm and db is different from one
another?
If they are different how can we minus the gain in unit of db from a
IP3 in unit of dbm?
Kindly enlighthen
Thank you all

rgds and thanks

Long, shallow buried radials are by no means a necessity.

Your dry, painted timber flag-pole, with a plastic insulated antenna wire running down it, can be located alongside a wall of your house or at the end, side or middle of the garden.

The soil should not be very dry and sandy but should be capable of growing common-or-garden flowers, shrubs or lawn grass. To improve the soil dig in compost or horse manure. A light sprinkling of copper sulphate won't do any harm except perhaps to the plants.

Lay a dozen or a score of 10-gauge or thicker radials, as long as you can and in as many directions as you can from the base of the pole. They will be useful even if only 2, 3 or 4 feet long.

Use bare copper wire, at a depth of a few inches in well compacted, trodden-down soil. Lay paving slabs on top if you like.

For multi-band use you will need an automatic tuner such as an Icom AH-4 located near the base of the pole. If the pole is mounted on a wall of the house the tuner can be located indoors in the dry.

(My AH-4 is mounted on the inside wall of the kitchen under the kitchen sink. It is also conveniently near to the main incoming water pipe which serves as my best of 7 short radials. The earthing loss resistance is only 6 ohms.)

The AH-4 (no electric motors - a set of relays) easily tunes a 32-feet unloaded vertical wire down to the 160 meter band. It is primarily intended for use in vehicles.

You don't HAVE to have an automatic tuner at the base of the antenna. You can use a home brew L and C matching network on an indoors window ledge by extending the vertical antenna wire sideways, above ground level, through the side of a downstairs window frame. The wire is then X feet longer.

There are a number of workable variations on the tune.

If you like amusing yourself with numbers, download in a few seconds program ENDFEED from website below and run immediately.

db is a generic term basically meaning: Decibel. A unit for measuring the relative strength of a signal. Usually expressed as the logarithmic ratio of the strength of a transmitted signal to the strength of the original signal. A decibel is one tenth of a "bel".

the key is that it is a ratio... without a reference a ratio is essentially meaningless. that is why you often hear that station a is 10db louder than station b... saying that station a was 10db wouldn't mean anything.

dbm has a built in reference. by definition: Decibels referred to 1 milliwatt.
so the reference is 1 mw. do you can say that the power of a source is 0dbm meaning that it is 1mw, 10dbm is 10mw, 20dbm is 100mw, -10dbm is .1mw, -20db is .01mw, etc.

i don't know an ip3, but maybe that will give you a start to know what you are looking for.

dBm is referenced to a milliwatt. dB is referenced to
something else and that something else must be specified.
dBd is referenced to a dipole. A web search for "decibel"
uncovered 100 dB of information.

Cut two pieces of 75 Ohm coax, 3/4 electrical wavelength long (about 38
inches for regular RG59). Connect one end of each to an antenna, the other
ends to a T connector. Connect 50 Ohm coax from third port of T connector to
radio; you will probably need a UHF F-F adapter to do this. Space the
antennas apart as far as the coax will reach. Anything less than 4 - 5 feet
is not worth doing. As I recall, one wavelength, 2 meter spacing, will give
almost 3 db gain.

Something wrong here. It would be very difficult to build anything at 440
MHz that has 2000 Ohm input impedance.

dB is a ratio for example dB = 10 log10 (P1/P2)
so increasing power from 100 watts to 200 watts is 3 dB (3.01dB actually)
But so is increasing power from 10 watts to 20 watts = 3dB
Since it is a ratio -- it is unitless

dBm is referenced to one milliwatt thus is a discrete power level

In the equation above P2 is always one milliwatt

Thus increasing power from 1 milliwatt to 2 milliwatts is 3dBm
From 1 milliwatt to 10 milliwatts is 10dBm etc

Not sure of your reference to ip3 but suspect you mean input third order
intercept point as used in amplifiers
Google ip3 to get explanations of this and how it is measured.

From off the top of my head, without any revision.....

IP3, or "Third Order Intercept Point" is an indication
of how good a mixer is, but it is not a physical point!

If you were to plot the wanted output of a mixer stage against
the input signal (ignoring the local oscillator input), you would
get a graph that is a nearly-straight line from the origin
which then starts to flatten off.

At the point of the line where it starts to curve over to
flatness, and therefore starts to be non-linear, other
mixer products, mainly those based upon the third
harmonic of the input signals start to appear in the
output. if you plot these other products on your graph in
addition to the wanted output signal, they grow at a rate (the slope)
which is 3 times greater than was the initial straight line
of the wanted output.

If you take the original straight line of the wanted output, and
extrapolate it so that it meets the other line growing at 3 times
the slope, you get what is known as the "Third Order Intercept
Point". The reason that this is a theoretical point is because the
wanted output has long since flattened off!

The better a mixer is, the higher is IP3 for the outputs of the mixer.

IP3 will be given in terms of the power of the wanted output signal,
say, 50 dBm - other respondents have informed you that this is
50dB (or 10^5) times greater than 1mW, or 100W (Perhaps not
a good figure for an example - a mixer with an output of those
levels could be a PA stage!). In this case dBm gives us the power relative
to the mW.

If we now go back to the flattening off of the curve, at some point,
the curve will be 1dB less than what it would have been had the curve
not been a curve but had carried on as a straight line. This point is known
as the "1dB Compression Point" - In this case we use dB and not dBm because
we are talking relative to some other point on the line.

There is a mathematical derivation (which I don't know off-hand) which
shows that the 1dB Compression Point is 10.4dB below IP3.

So, I hope that I have gone some way to explaining (or increasing your
confusion) on the points that you raised!

Cecil is CORRECT, also, other terms you might run into are:

dB I = dB Isotropic (an immaginary point source that radiates
in all directions uniformly) , used for antennas.

dB W = dB, gain or loss , referenced to 1 Watt.

dB is simply the logrithmic ratio of (POWER, Voltage) to
the reference (-1 dB = a loss of 1/10 of your power, -3 dB ,
loss of 1/2 your power, and if positive, the opposite is true
1 dB = 10% power gain, 3 dB = twice the power, ect.
as info, Jim NN7K

1936. Low dipole performance question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-04 17:20:44 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <M9OMd.2187$GT.297@okepread01>
Source record: 82524

As I understand it, my dipole shoudn't work - it's flat (non inverted V), it's laid out running east / west so the radiation should be going north and south and it's only 20-25 feet above ground.

The antenna is a coax fed (no balun), 220' long 80/160 trap dipole.

By my way of thinking, this antenna should almost be a NVIS antenna.

If so, how did I manage a QSO with K7NN on 1.893 last night? Tuscon, AZ from Wichita, KS on 100w. EM17ip to DM42li on 160m at 04:00z

Am I missing something here?

The enjoyment of such an "impossibility?"

Hi Ken,

The how you are asking for could go by any number of explanations, and each may sound as plausible as help from Extra Terrestrials. One way to look at your antenna description (especially with the up front declaration of no choking) is that you have a top loaded, tuned T antenna (vertical instead of horizontal) planted in the highest conductive soil in the U.S.

One could only wonder if you couldn't accomplish what you did.

From a circuit operational point of view, could you please summarise in what way a high IP3 makes a better mixer?

Am I correct in assuming the device need not be a mixer? Could it be an amplifier? In which case some of the better or worse parameters would just become meaningless.

Reg.

To elaborate, P2 above must be 1 mW only if one wants to calculate dBm.

The equation as it is written above will calculate the relationship in decibels between any two power values expressed in the same units. For example, to find the gain of an amplifier in decibels when its input power is 50 watts and its output power is 1.2 kW:

dB = 10*log(1200/50) = 10*log(24) = 10*1.38 = 13.8

Hi Jim,

I must've missed something here with this dimensionless, referenceless declaration. I'm not even sure if there isn't an implicit negative sign to it.

Would this be 100dB above ignorance? 100dB below genius? What is the zero reference for information? Valid information, and simply available information is not exchanged at the same rate (100dB above entropy?). It can't be zero information because that would cause the computation to be "undefined." Hmmm, maybe the baseline is the computation of no information. -No- That returns us to the conundrum of even what is 1dB above "undefined?" SWAG? In that regard:
>> A web search for "decibel" uncovered 100 dB of information re SWAG

Can there be a ratio of 1 SWAG : 10ï¿½ï¿½ Facts? When I enter the universal measure of knowledge into Google, it only returns "19,400,000 for TITS." This is roughly 500 times below the declaration made above. Does it follow you must perform 500 SWAGs to successfully achieve your goal of TITS? This sounds almost about the same as the computation of probability for a teenage boy on a date running out of gas on a dark road - and yet historically this occurs far more often than chance.

I thought about that since I don't use a balun (I know, I know -
I should). My feedline drops 20' down from the feedpoint then
runs ENE to my house for 40'. I've thought about a balun but
I only use the antenna on 160 & 80 and it seems to work well
so I don't want to mess with sucess.

Small light bulbs live in a different world. For instance, many flash lights use a bulb that is rated for a lower voltage than the battery. I have one that uses 2 AA cells and a 2.4 V bulb. This makes it brighter, and if the life of the bulb turns out to be 10 hours, that is inconsequential, because 10 hours of use is beyond the life expectancy of a flash light. You probably should have bought a 14 V bulb, since you do care about bulb life.

1946. Testing for gain/loss in an antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-04 18:28:21 UTC
From: Buck <iam@this.site>
Message-ID: <h7f701d50v81rampj33ogferfk5vc1hl9v@4ax.com>
Source record: 82535

I want to test a couple of antenna designs and compare them to a dipole antenna.

I am wondering if my idea is a good way to measure gain or loss from an antenna. Here goes:

Create a place in which to install the test antenna which will be consistent. For example, 40 foot high between two power poles (no power lines etc, though.)

Setup a fixed location with a Field Strength Meter (FSM) that has a fixed antenna for testing at that location.

Hang a dipole (the reference antenna) and transmit a signal that can be calibrated to a fixed location on the FSM. Then hang the experimental antenna in place of the dipole. Take the measurements without changing anything from the rig. Measuring the power output required to meet the same setting on the FSM as the dipole should give me a fair idea about the gain or loss from the experimental antenna.

or maybe not.

What am I overlooking?

Thanks

YES, It's called Propagation! :)

I was on 75 last night with a similar situation for 75 meters. I
wasn't heard by stations in the southeast, an area I usually cover
very well, but instead had to pass traffic to Illinois to be relayed
to Alabama to be relayed to Kansas. Lots of long skip but I couldn't
talk 60 miles to Columbia, SC.

100 dB compared to the answers one gets on a newsgroup. :-)

1949. whip antenna calculations

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-04 18:46:50 UTC
From: Spam Fighter <spamcollector@sympatico.ca>
Message-ID: <pan.2005.02.04.18.46.49.542745@sympatico.ca>
Source record: 82538

I am looking for a .xls spreadsheet (or something that works under LINUX), to calculate the equations for matching common maritime mobile HF whip antennas:

8 ft
10 ft
15 ft
23 ft
40 ft (backstay, approx 5/8 on 20 Meters)

I want to calculate the matching parameters including voltages generated in the tuner for the 1.8 3.5 7 10.1 14 21 28 MHz ham bands and the 2 4 6 8 12 16 and 22 MHz marine bands.

The ARRL ANTENNA HANDBOOK, 18th edition, chapter 18, has some equations and a table of calculated values for a 8 ft whip on ham bands. I wish to duplicate the calculations and figure out the voltage maximums for component values for, say, 100 W key down power.

Take for example the 1st row of the table:

BASE LOADED 8ft whip
F=1.8 MHz
Loading L = 345 uH
Rc Q=50 = 77 ohms
Rc Q=300 = 13 ohms
Rr =0.1 ohms
Feed R = 23 ohms
Matching L = 3 uH

Now at 1.8 MHz
XL of 345 uH = +j3902 ohms

Do I calculate the current from P=I*I*R so for
Rr = 0.1 ohms, I = sqrt(100/Rr) = 31.6 A
so V XL is I*R = 31.6*3902 = over 123 KV? (seems excessive)

or do I use the R values of 77, 13, or 23 ohms? (4.4 KV, 57 KV, 8.1 KV)?

Do I multiple all RMS voltages by sqrt(2) to convert RMS to PEAK?

The spacing of these antennas is so close at to make it hardly worthwhile-
as Tam points out in a following post. For simple omnis, or dipoles, the
stacking gain peaks around 4'-->5' at 2M. A first shot at modeling shows
that the gain increase from stacking 2 omnis at 27" is around 0.5dB-
assuming a lossless matching network.

One common house-building style around here (California) uses a
building frame of 2-by-4 or 2-by-6 wood, with an outer layer
consisting of stucco which incorporates a galvanized-steel "chicken
wire" mesh.

I'd encourage keeping HF vertical antennas well clear of any walls
made in this fashion.

Raleigh fading? (Addition or subtraction of reflected signal from the main - or flutter you hear on VHF)

You dont mention the freqency in use or the distance between antenna and FSM. There is some kind of optimum or minimum distance (in wavelengths) that I dont remember off hand

You dont seem to be allowing for ground effects and the desired angle of measured radiation. (If that is important..)

Having said that how you have described it is probably how I would attempt it!

Cheers Bob VK2YQA

I have had to deal with the same situation and I found that ground moisture plays a big part in making the ground radials work, no matter the length. I picked up a couple 50 pound bags of rock salt, sprinkled it in and around the radials before covering them up and it worked like a charm. Don't be stingy with the salt... and it didn't even kill the grass. The longer the rock salt stays in the ground the better the antenna worked. A good watering down of the area is enough to start the process. If you live in a dry climate an occasional watering also helps. Sure the salt will corrode the wire but before that happened I'll probably be an SK.

That's my 2 cents worth but it worked for me. I've got up inverted Vees at one home now and can really appreciate the real estate. I'm on the east coast (VA) and have worked VK & ZL with 100 watts on SSB 75 and 40 meters.

Pretty good explanation for a mixer, however, IP3 relates equally well
to amplifiers.

In receivers, IP3 is used as a figure of merit and describes how a
receiver will handle weak signals in the presence of other stronger
signals. It is as explained earlier, a theoretical value.

Hi Ken,

As you are finding out, "working" is a variable definition. Optimum antennas would be 6 elements a mike high, but antennas do work at all heights above ground, and with the help of propagation can do great things. All my antennas are below 40 feet off the ground and I still make contacts, including DX contacts, with vertical and wire dipoles and a G5RV.

Good luck and good DX,

Bill, W4WNT

I just acquired a used Isotron 40m antenna. Set up on a plastic pipe on the deck, 13 feet off the ground. I've worked VE2, EA8, and KP2 on CW. Receive signal is about 2 S units below an R-7000 in the back yard. Next step is to get some electrical conduit and build a 20 foot mast to see how that works. Instructions (available on the Internet) say it needs a metal support to get the correct impedance.

Hi Airy -

I generally agree with your description of IP3; but I would add
a few points.

The IP3 model was first published in a now-classic article
back in the 60s. (I could probably dig up the specific
reference, if someone really wants to know.)

The original author observed that many practical devices
(e.g., mixers) exhibit distortion levels that rise as the "power"
of the product in question. For example, third-order distortion
rises 3 times as fast (dB scale) as the desired (linear) signal.

If the subject distortion is plotted against input/output levels,
and approximated by a best-fit straight line, that line will
intersect a similar linear extrapolation of the desired signal
at a point dubbed the "Intercept Point."

The utility of all this is that you can use a single specification--
intercept point--to make quite good predictions of distortion
levels over a wide range of input conditions.

But it is important to remember that IP is only a MODEL,
and an empirical one at that. Real devices will never follow
the model exactly and completely--as you note in your
discussion of the saturation region.

> From a circuit operational point of view, could you please
> summarise in what way a high IP3 makes a better mixer?
>
A higher IP3 simply means that the hypothetical mixer can handle bigger signals before it produces a given level of 3rd order IM distortion products.

Whether or not that makes it a "better" mixer would depend on many other specifications, such as noise figure, loss/gain, bandwidth, and even size and power consumption.

> Am I correct in assuming the device need not be a mixer?
> Could it be an amplifier?

If you're asking whether other components such as amplifiers can have IP3 specifications, the answer is definitely yes.

> In which case some of the better or worse parameters would just
> become meaningless.

I can't figure out what you're trying to say in this last sentence. But correct and relevant specifications are never "meaningless." (At least I can't think of any such pathological examples.)

Hello to all that Helps
You are all very kind and genius.
It is first time I asked question in newsgroup and I received so many
kind answers.
I am so happy. Thanks a lot

So from what you have all explained, can I bold enough to say that I
can add any value in db and any value in dbm together without
converting to one db or dbm unit because they are in the ratio form and
having virtually the same 10log (P1/P2) formula and nothing else more??
Please verify

Thank you

rgds and thanks
Jason

Dear Jason,

I am sorry to say that I cannot agree with your conclusion.

In my opinion, in the general case, you can NOT add dB and dBm. They have different applications and were not intended to be added together.

A quantity expressed in dBm is intended to convey, or imply, a specific power level in a specific load impedance. On the other hand the dB is NOT so defined. Therefore, I cannot think of a situation in which you could simply add them together and have a result that anyone would be able to iterpret at face value.

You seem to be under the impression that an antenna fits into only one
of two categories, "works" and "doesn't work". That's the first mistake.

You also seem to believe that all the power you radiate goes in only one
direction or at one elevation angle. That's the second mistake.

Once you learn a little about the basic operation of antennas, and how
to interpret a radiation pattern, the answer to your question will
become clear.

'

It is for testing HF antennas, but no reason it can't work for VHF as
well.

After writing this, I was thinking of the G5RV, it has a cloverleaf
pattern so it might register as a loss since the antennas would be
broadside to each other.

I don't know the distance for the FSM. I suspect it would have to be
a good distance away. probably a wave length or more.

This would work best with a beam antenna as the lobe would be
consistent. but a 3/2 wave antenna would have different radiation
lobes so it might register a loss instead of the gain it actually has.

It is a thought, but I may have to reconsider it.

Thanks

<Snip>

Ed, where the increasing intermodulation distortion is simply a result
of increasing the level of the signals at the input of the mixer (or
amplifier), third order distortion actually rises TWICE as fast as the
desired signal. Third order distortion DOES rise on a 'three dB per dB'
basis, but the wanted signal also rises - at 1dB per dB. The difference
is 2dB. So the relationship is 2dB per dB.

If you continued to increase the signal levels, you might expect that
the level of the intermodulation would eventually catch up with - and
overtake - the level of the wanted signal (it doesn't, of course).

The third order intercept point is simply the hypothetical level where
the level of the intermodulation would have risen so much (at 2dB per
dB) that it equals the level of the wanted signal.

Hello, thank you for reading this post.

When analysing wideband impulse signals from a wideband antenna I have realised that the average signal magnitude is not zero. I have thought this is because the reactance of the antenna at different frequencies varies and since it is a wideband antenna there can be energy measured since it is only for an extremely small period of time of 2-4 us. However, I am not sure and would greatly appreciate the views of this newsgroup.

Hi Ken,

As many have already pointed out. Propagation conditions account for a lot. but you also have some misconceptions.. a dipole on 80 or 160m that low to the ground exhibits almost omni directional patter not much of a lobe off the sides. So the orientation is not all that important.

high angle radiation can work out quite well on the low bands at times, and is useful under certain conditions. I've found here that my Vertical on 160m is not always the best dx catcher. sometimes not often the dipole beats it out on DX signals.. it all depend upon propagation condx. As one old timer told me many years ago.. the Ionosphere is a get leveler of signals.

73 Dave Kc1di

P.S. the Moral is not give up trying if your antenna is only 40 or less feet in the air a great number of hams around the world are in the same boat. There calls may not ever be in the top 10 of the DXCC list or winner of the Weekend DX test , but they have lots of fun. and part of the fun is the unpredictable nature of radio waves.. I've always found it interesting to call CQ and have someone answer weather it's next door or around the world. it's still fun :) Sort of like fishing isn't it.

I dont know where YOU got your antenna info from....but just because a dipole has wide b/w (low Q) does not lower its gain unless the diameter of the dipole causes the resonant length to be much shorter than 1/2 wavelength...but in practical terms, that wont happen (unless he makes the dipole out of 4 ft pipe for instance! ;)

A wide b/w (fat) dipole made for 80m (a cage dipole) does not have any less signal strength than a single wire dipole (2.15 dbi).....sorry.

The formula for a DIPOLE is 468/freq in Mhz = length in ft.....the formula
234/freq is for one leg OR usually quoted for a 1/4wave vertical but the
standard dipole formula is 1/2 wave (just to clarify that).

As for a good FM omni antenna, he should build a simple 1/4 ground plane or
coaxial sleeve antenna.....OR a turnstile (cross dipoles)..

FM stations USUALLY use Circular Polarization.....(similar to horiz and
vertical at the same time...)
so an antenna set for horiz or vertical will work (but lose 3db of signal
compared to a CP antenna!)

The algebraic summation of decibel values is a mathematically legitimate, and convenient way to determine system performance. Decibels are based on logarithms. Adding/subtracting logs or (decibels) is easier than manipulating the real values they represent. The final dB value in an analysis can be converted back to whatever units are desired.

For example, below is an analysis of a UHF radio link system over a free-space path. The 5 watt power of the transmitter is first converted to dBm so it can be used with other dB values present to analyze the system. The same result is reached when multiplying tx power in watts by system gains and losses expressed as decimal values, but that process is more awkward -- at least when using a pencil & paper or a pocket calculator (computers don't care).

TX PWR OUTPUT 36.99 dBm
TX ANT 19.20 dBi
RX ANT 19.20 dBi
TOTAL GAINS 75.39 dB

DISTANCE 18.00 Miles
FREQ 950.00 MHz
PATH LOSS 121.26 dB
LINE LOSS TX 1.80 dB
LINE LOSS RX 3.00 dB
CONN LOSS 1.00 dB
OTHER 0.00 dB
TOTAL LOSSES 127.06 dB

RX SIGNAL -51.67 dBm (584 uV)
RX SIGNAL REQ'D -90.00 dBm
RAW FADE MARGIN 38.33 dB

Hello Ken ....My OCF dipole at the same height can only be categorized as a real piece of crap.
Hopefully I can get something up better in the near future but that depends on the neighbor's cooperation
with using a maple tree in her yard. I ran inverted vees for 30 years at 40 to 50 feet and have had excellent results
on 80 and 40. I am glad to hear that your set up is working.

Concerning the loopstick RX antenna identified as "VLF to Longwave:
Wideband Tuner" shown at:
http://www.stormwise.com/widetune.htm

I was told that the tap at 10% was to provide a match for a receiver
expecting a 50-ohm antenna.

Would I achieve the same result by using 405 turns, no tap, and a 9:1
current balun?

I am building a tuning cap box that covers from 25pF to 2uF in 25pF
increments. I am hoping to cover from 9kHz to 30mHz using the
variable capacitor box and 1,000 turns, with intermediate taps at 10,
33, 100, and 333 turns -- to be used as appropriate for each band.

FM broadcast stations in the US _must_ radiate their licensed h-pol ERP regardless of the ERP they radiate in other polarization planes. However for most omni FM stations, v-pol RMS ERP cannot (legally) exceed h-pol RMS ERP.

The gain of a true c-pol transmit antenna is 3dB lower than for the same configuration of linearly polarized radiators. However in FM broadcast, the transmitter power is increased by 3dB to make up for that, and h-pol ERP is the same for either antenna configuration. Therefore the h-pol field strength produced by either transmit antenna over the same path should be the same.

Using a c-pol antenna to receive a c-pol FM station would add 3dB to the signal seen by rx (over a free space path), as well as reduce the self-interference caused by multipath.

>
>rgds
>Jason
>

Think of it this way:
dBm indicates an absolute value. db indicates a relative value.
For example:
0dBm = 1mW
0dBm + 3dB = 1mW x 2 = 2mW = 3dBm
0dBm + 10dB = 1mW x 10 = 10mW = 10dBm
3dBm + 10dB = 2mW x 10 = 20mW = 13dBm
20dBm - 30dB = 100mW/1000 = 0.1mW = -10dBm

What you can't do is to add dBm values directly.
If you have power combiner, and add 10dBm and 13dBm, you can't add 10dBm
and 13dBm and get 23dBm. 23dBm would be 200mW (because 20dB is x 100,
3dB is x 2, so 100 x 2 =200), and this is incorrect.

What you have to do is to convert the dBm values into mW, then add the
mW.
10dBm = 10mW
13dBm = 20mW
Total power = 30mW (and not 200mW)
30mW can then be converted back into dBm (= appx 14.5dBm)

Do you see the pattern?
Ian.

Have you tried Cubex? www.cubex.com They make Quads and sell fiberglass spreaders and have a boom listed for 44.95. It's 13' however. Contacting them may be helpful as they may have a crushed/broken mast where 5' or so is good and sell it to you to recover some of the loss.

He seems to be saying the DC value is not 0 for a sampling
time period of 2-4 uS which would of course be true for a
sine wave if, e.g., an odd number of positive cycles were
sampled along with an even number of negative cycles. Or
if the frequency was lower than 250 kHz. Plus all the
signals and noise are superposed.

>there is new contribution? No email notify me on this. How to do the
>correct setting?

Assume that your system has IP3 = X dBm measured at point Y in the
system.

Assume further that there are amplifier stages A and B following point
Y, and that those amplifiers contribute a gain of A dB and B dB.

At the output of B the power level, in dBm, will be X + A + B.

In this way you avoid the confusion by clearly stating that the power
level at the output is X + A + B. In that context, the values can be
added, because you have made it clear that it is a power level in dBm
- not a gain in dB.

Regarding the auto-notification. I do not know of any such system.
Perhaps that is an opportunity for someone to develop a valuable
product.

I don't know the answer to that, and you are as capable of
looking it up as I am.

If an amplifier, then perhaps you'd run into clipping problems
or rail problems before non-linearity?

First of all, my apologies. As you can gather it is the first time I post in this newsgroup. In the process, the computer kept on telling me that I required authentification (I had forgotten to click on one of the boxes) and said that it could not send the message. I therefore ended up writting it several times. As it turned out, two of the times where it told me it had not sent it, it had. I greatly apologise for all the inconvenience.

Secondly, yes, I mean to say the signal has a DC component. I would have thought that impulsive noise, being cause by electron movement would produce an AC signal, otherwise where does the DC come from? The importance of the time is because I would have thought that in the long term the antenna would resonate so as to produce a zero mean signal (AC). Sorry, the answer might be common sense but I just fail to see it.

Thank you for your time and once again, sorry.

You could start off with a signal measured in dBm, perhaps
the output of a transmitter.

Thereafter you could add and subtract anything in dB (but NOT dBm).

Here's an example (my figures are made-up and not intended to
be realistic). let us calculate the E-M-E signal strength of our
transmission bounced off the moon.

TX output = 1000W = 60dBm.

Antenna gain (Assume a big dish) = 50dB

Effected Radiated Power (ERP) = 110dBm

Path loss to Moon = 80dB

Path loss due to bouncing off Green Cheese = 30dB

Path loss back from Moon = 80 dB again

Total path loss = 190dB

Antenna Gain = 50dB

Received Signal Strength = 110 -190 + 50 = -30dBm = 1 uWatt.

So, we started off with dBm, then added or subtracted dB (which
gave us dBm again, but we only added or subtracted dB)

Why, Thank-you!

In the case of amplifiers, presumably we are talking
about the effects of unwanted strong signals driving the
amplifier into its non-linear region (and therefore acting
as a mixer)?

Let's talk loosely, and talk about money.

If I've got twice as much money than Ian has, then
I've got 3dB more.

How much do I have? Don't know.

If Ian has three times as much as Richard, then he
has 4.7 dB more than Richard, and I have 3 + 4.7 =7.7dB
more than Richard.

How much do I have? Don't know.
How much does Ian have? Don't know.
How much does Richard have? Don't know.

OK, assuming that we could deal in 1/10ths of a cent (1 milli-dollar!)
let's assume that Richard has $100 = 50dBm.

Ian therefore has 50 + 4.7 = 54.7 dBm.
And I have 54.7 + 3 = 57.7 dBm.

The answer to your question is that you can start off with an
actual reading in dBm, but everything else relative to that is
in dB only (although it does give a result in dBm).

If the above doesn't answer your question, then, sorry,
but I give up. (Which doesn't mean that my interest is 0dBm
but -173 dBm, ie, indiscernible below the noise)

yes, a signal can have a dc component, even from a small antenna. (just watch the arguments over this one) it gets even worse if you sample over a short period like a few microseconds depending on the characteristics of the signal you are measuring. and it can get much worse over a long period because of numeric integration errors accumulating, or small measurement bias in instrumentation accumulating.

I can understand all you are saying but in this case it is am impulsive wideband signal (500 - 2.5 GHz), with a defined start and finish, caused by, say things like car ignition systems and faulty thermostats. Surely a signal like that would have all frequency components starting and ending at a zero-crossing and then have full cycles, wouldn't it? Or maybe not because of the multipath effects? Do you believe this can be the case in my situation?

Thank you.

The DC is the result of your 2-4 uS sampling window. Make
your sampling window one second long and see what you get.

For instance, if you sample a 250 kHz signal for 2 uS and
if you happen to hit it at a zero-crossing going positive,
you will read the DC RMS value of the wave, having sampled
only 1/2 cycle.

On Sat, 5 Feb 2005 16:55:35 GMT, "Galilea" <iportu@hotmail.com> wrote:

Hi Galilea,

You give the impression of being under the spell of a lot of
illusions. As you appear to be writing from an academic institution,
you should have been educated in the first principles of engineering:
a well described problem contains its own solution.

What you have been describing through your series of postings are
simple musings or rambling thoughts, nothing really coherent.
Stringing facts together does not really describe what you are
seeking. Let's examine this by parts:
>I can understand all you are saying but in this case it is am impulsive
>wideband signal (500 - 2.5 GHz), with a defined start and finish,
This is specific, detailed and uninformative. By definition, an
impulse has a defined start and finish, so nothing of value is added
by making such a declaration unless this start and finish are somehow
out of the ordinary. When you continue with:
> caused by,
>say things like car ignition systems and faulty thermostats.
"Like?" This is inspecific. Further, ignition systems and
thermostats have very little power in the spectrum you describe
(unless picoWatt levels are a disturbance to your true concern - if
so, this should be put on the table and all these abstractions swept
aside).
>Surely a signal like that
Like what? This is becoming speculative without a basis.
>would have all frequency components starting and ending at a
>zero-crossing and then have full cycles, wouldn't it? Or maybe not because
>of the multipath effects?
Here is every evidence of intellectual fishing because the answers to
your questions should be reasonably yes, but in actuality is no.
However, that yes/no aside, it is immaterial as this answer relates to
no larger over-riding question:
> Do you believe this can be the case in my
>situation?
No one knows your situation because you have no where described any
context to this string of statements, conflicting observations, and
speculations.

Basically you have offered a story with all middle and no beginning
and no end (somewhat mirroring much of the angst of your internal
conflict). Discard all these answers you are trying to force into
your problem and simply describe your problem.

First, how did you become aware you had a problem? Describe the first thing that seemed unusual. Don't give us the theory of why - subjectivity will always dominate the first impression and is fine as an introduction.
Good Example: "I saw smoke."
Bad Example: "It was violating entropy."

Second, What else did you observe? Describe all other characteristics, good and bad.
Good Example: "There were no flames, and it was unplugged."
Bad Example: "The Butterfly Effect would suggest that perhaps a nova might be contributing to the imbalance of energy."

Third, Offer supporting details of measurement. Describe your configuration, your tools, your method, and your results.
Good Example: "I examined my hair dryer; using a thermometer that I placed at the exhaust; and found it read 300ï¿½C Over several minutes it fell to 100ï¿½C and continued smoking."
Bad Example: "The thermal emission did not balance with the absence of the standard power application of 900W."

Fourth, Describe those components that are directly involved in conjunction with the observations and those that bear no relation, but are supported by normal observations.
Good Example: "Cooling is evident from it not being plugged in, however smoke is evidence of a continued process related to the heater."
Bad Example: "Since there was no power in, there should have been no power out. Isn't this a violation of the conservation of energy?"

Fifth, Localize the problem through refinement of measurements. Split the problem in two and examine characteristics. If you obtain normal data, split the problem in two again between this point and the source of problematic data and repeat.
Good Example: "On close inspection I observed a long ash."
Bad Example: "I plugged it in and the imbalance of entropy became dramatic."

Sixth, Describe the probable cause.
Good Example: "Hair had been drawn into the inlet and ignited by the heater."
Bad Example: "There is every indication that a possible nova, through the Butterfly Effect, created an imbalance in the continuum of energy such that local effects produced a surplus bias of caloric emanation."

Hi Ken,

I wasn't sure if your 30mHz was meant to be milliHertz or not, but given the focus found at your link above, I presume you seek to listen at the ELF and below.

When I looked at the truly meager coil offered at that site, I took up my pen (metaphorically) to suggest you need something very, very, very much bigger. 450 turns is truly pathetic. Some years ago, Scientific American's column described a project that required 10000 to 20000 turns on a three foot ferrite rod.

However, none of this actually responds to your question about a 9:1 BalUn (and a current BalUn no less). This is waaaaaay out of the common. (Read this will not be found off-the-shelf except at a specialty store.) At these frequencies, standard transformer design is suitable to design and construction details. Your stated need for it to be a current BalUn would suggest your need for isolation. Consider that those leads will need at least 3X and preferably 10X the impedance observed in the coil you construct if that is what you are trying to isolate. This means 50000 to 100000 turns of a wire pair around a similarly long ferrite. Do you have the patience? ;-)

If the antenna is very wideband and isn't acting like a filter,
you can do a Fourier analysis on a series of pulses and decide for

yourself whether there is a DC component or not. Or, if there's only one pulse, you can use the Fourier integral to find the amplitude distribution across the frequency spectrum. I don't think you should be too surprised to find a DC component in a series of pulses, or even in a single pulse.

Just wondering i am putting a dipole on the roof of a 12 story building
i'll mount it around 30ft off the flat surface of that roof

my antena will be about 150 ft off the sidewalk

when trying to calculate my dipoles hight is it above the roof surface
or 'real' earth /sidewalk ground that 'counts'??

thanks

Hi OM,

If you were on a step ladder putting up the antenna, which would feel worse if you fell? Hitting the roof or hitting the sidewalk? That is how much it counts.

Another point of view is if you were to shine a flash light from your roof, or from the sidewalk, which would offer a greater chance of being seen a mile away? That is how much it counts.

However, there are complexities beyond these sophisms. How much chance would your flashlight have being seen if you were obstructed by a penthouse? Hence there are factors that reduce the effectiveness of your antenna on the roof. The question is how much - which is a question everyone has to answer for their own situation. The difference here is that even if you suffer equally with everyone else, you still have the advantage of height. So, barring a horrible situation on the roof, you enjoy a net sum gain.

You would most likely get better results using the roof as a ground plane
for a vertical.

==========

Just take the geometric mean.

Effective Height = Sqrt(150 * 30) = 67 feet.

But what you do with this number hardly matters two hoots. What do you have
in mind to use the number for?

Just continue to do as you intend and I'm sure the antenna will work fine.
It's very few people who have a starting point of 150 feet.

Reg.

This is for manmade RF from 9 kiloHertz to 30 megaHertz. So, we are
talking VLF, LF and HF. A member of my ARC has temporarily wrapped
one of these ferrites with 50 turns of 22 ga. and is getting terrific
reception all over the shortwave bands.

I have seven antennas up right now so there is only one spare run and
one spare run for a rotator.
I would guess conduit would be ok but for what I have it's not needed.
I can replace a run here by soldering the center and outer shield to the
new piece and pull it through with out any problems, if the cables had
been run other than the way they are now then conduit would have made
things easier.

Hi Ian -

Thanks for trying to clarify, but I think you misread my post
somehow.

I said "...third-order distortion rises 3 times as fast (dB scale)
as the desired (linear) signal."

You said "Third order distortion DOES rise on a 'three dB
per dB' basis, but the wanted signal also rises - at 1dB per dB."

The content of our statements is the same. But you went on
to address the slope DIFFERENCE, which I did not discuss.

I believe Airy is making the same point I am making here
with his (2/5/05 8:25) post.

Hi again -

A couple of added thoughts here:

1. The term "mixer" has at least two quite different definitions
in the electronics world. To the RF guy, "mixer" means a nonlinear
and/or time-variant device that is used to create sum and
difference frequencies between an input signal and a local
oscillator. But to the audio guy, "mixer" means a highly linear
device used to add or combine audio signals WITHOUT
producing distortion products.

2. As implied above, an RF mixer does not have to be nonlinear;
it can also be implemented as a linear/time-variant device.
(Think of a highly linear switch being chopped at the LO frequency.)
However, the most common practical mixers are those that can be
modelled as non-linear/time-invariant and those that can be modelled
as non-linear/time-variant.

Hi Airy -

I'm not sure what "answer" you're referring to here. But if you're referring to the question about IP3 applying to amplifiers, the answer is a resounding "yes"--as noted in posts above.

As a matter of fact, IP3 is often most useful when applied to an entire chain of cascaded devices such as mixers and amplifiers.

Regarding your comment about an amplifier possibly "clipping... before non-linearity," that is impossible by definition--because clipping IS a non-linearity.

But it is possible to find amplifiers that are extremely linear below clipping, and which clip very abruptly. Such amplifiers may show relatively poor conformity to the intercept point model, which was based on more gradual nonlinearities.

2034. Re: average signal magnitude not zero

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-06 02:22:20 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <110avqvm87pke8d@corp.supernews.com>
Source record: 82423

The average value of a signal is its DC value. To receive and reproduce a signal with a non-zero DC component means that your antenna, as well as your receiver, has to have response to DC. To generate such a signal would require a static electric and/or magnetic field, which can't propagate. So it's not possible for a signal you're receiving to have a non-zero average value.

If it doesn't seem to be zero, there's something wrong with your measurement system.

> wavelength...

Here's a quiz question: Suppose the dipole could be made fat enough to reduce the resonant length to 0.01 wavelength. How much would the gain be reduced?

Part 2: Suppose the dipole remained the same diameter and was reduced in length to 0.01 wavelength. If the conductor were perfect, how much would the gain be reduced?

Hint for Part 2: This is easily answered using the free EZNEC demo program, another modeling program of your choice, or a few minutes' reading of just about any antenna textbook.

I think you are correct. Either that or a rotatable antenna. :)

If the antenna is supposed to have a clover leaf pattern, then maybe
just setting up the FSM in the angle of the lobe.

Just a thot.

Source record: 82427

Not unusual really.
I wonder if he's actually resonant through the
whole HF spectrum though. Doesn't always actually
have to be resonant to "work". But tuned is much
better, naturally. I have to wonder why
they call it a tuner...?? It's an antenna as far
as I'm concerned.
Along the same lines as a ferrite antenna in a
radio, just bigger, or box loop, etc...
I did try making a MW antenna on a PVC form for MW.
Actually, it was a coil wound on PVC that was once
used for a short 160 dipole...
About 90 turns of 14 about a foot long. Tuned it
with a variable cap..It worked ok..
But a box loop is much better I think...You think one
of those little PVC wound loops is good?
Wait till you try a big box loop. But I don't normally
expect to cover the whole HF spectrum with a box loop.
I have one loop in the room here, that is a 44x44 inch
diamond, on a rotating stand. I use a multi gang
variable, that has a switch to allow using only a
single low value cap for the upper range of the loop.
I also have fixed caps I can tack in parallel to drop
down into LW. The loop has 7 turns, and is basically
designed for MW, using the average cap, but in all,
mine tunes from about 200kc to about 2150 kc in it's
present form. On LW, MW, or even 160m, it's quite a
bit better than the small PVC loop. It can be fed
indirectly using a built in ferrite loop as the
coupling loop, or can be fed with coax, etc...Mine are
all fed with coax to a coupling loop inside the main
loop, and I don't bother with baluns, etc.
They are not needed in most cases.
I don't normally use small loops for anything above say
2.5 mhz...A dipole, or even a random wire is usually
much better above that freq.
There are many designs for box loops, and Reg has
a good program for calculating the turns needed, etc.
I think it's rjeloop3.exe, if I remember right...
I have one fairly simple PVC design at:
http://web.wt.net/~nm5k/loop5.jpg
It's pretty easy to slap together. I never cared
much for the overly complex octagon designs much..
More work than is required...:/

BTW, the VLF natural noise stuff is kinda
interesting.. I might try to cook up something
for that...Never have listened down there.

I've been extremely busy lately, but found a few minutes to run this.

This is for a 33 foot vertical with 33' ground wires buried 6 inches deep. The model was run with EZNEC/4 using the NEC-4 calculating engine. All are for average ground, and the gains are at the elevation angle where gain is the maximum -- 26 degrees in all cases.

With one radial, the gain in the direction of the radial is -5.94 dBi, -6.7 dBi in the opposite direction. It's interesting to see how much difference it makes to have the radial just a foot above the ground, as Cecil modeled, rather than six inches below. When the radial is above the ground, the current distribution looks pretty much the same as the vertical wire's. So it contributes significantly to the pattern. But when buried, the current decays rapidly in an exponential-looking fashion, so it doesn't contribute much to the radiation.

With one radial, the gain at right angles to the radial wire is -6.49 dBi.

With two radials, the gain in line with the radials is -4.33 dBi, and at right angles essentially the same, -4.58 dBi.

With four radials, the gain is -2.95 dBi essentially in all directions.

With 8 radials, the gain is -1.79 dBi. This is just about what you get in the favored direction with a single radial elevated one foot. According to NEC-4, anyway. These would be some interesting experiments to do with a real antenna.

And, running EZNEC using MININEC-type ground gives the gain you'd get
with a perfect radial system -- -0.02 dBi.

2043. SUPER J-POLE BEATS YAGI BY 1 dB

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-06 13:42:42 UTC
From: radio913@aol.com
Message-ID: <1107697362.650524.93750@z14g2000cwz.googlegroups.com>
Source record: 82432
Cross-posted to: rec.radio.amateur.antenna,alt.pirate.radio,alt.radio.pirate

Hi,

Well, our Super J-pole:
http://users.marktwain.net/aschmitz/antennas/jpolecalc.html

Is beating our Yagi in ALL directions,
even in the forward lobe!

Here is the theoretical H-plane plot of our Yagi:

http://www.drslick.org/Temp1/yagiplot.jpg

And a photo:

http://www.drslick.org/Temp1/yagi929.jpg

So if you assume the theoretical
2.5 dBi of a regular J-pole, then the Super
J-pole has about 3 dB over that, so about
5.5 dBi all around.

So we have about 4.52 dB in the
forward lobe of our Yagi, so even there,
we beat it by about 1 dB with the Super
J-pole. That's like 238 watts versus
300 watts.
It's even worse in the back
lobe, where it's a -12 dB difference.
That's like 19 watts versus 300 watts!

It's only a theoretical
yagi optimization plot, and i don't think
it sounded like 19 versus 300 watts in the
back, but it's a BIG difference, even in the
areas that were already strong....almost
full quieting.

And yeah, we didn't really optimize
the yagi for a strong, narrow lobe...it was
designed for a 180 degree pattern, so the
gain ain't great, but you still have some
control over directivity. It's still
not really a fair comparison.

At any rate, if you need an
omnidirectional, i highly recommend the
Super J-pole!

Here's another site if you are
interested:

http://www.geocities.com/n2uhc/jpole.html

Questions and comments appreciated!

Pure DC doesn't radiate, but there can be a DC component in the modulation of an RF wave that does radiate. An example is analog broadcast television, which has a highly asymmetric RF waveform. It can transmit a constant (DC) video value of any amplitude between reference black at 75% modulation and reference white at 12-1/2% modulation.

Please explain how this design is directional. It should be essentially omnidirectional in the horizontal plane, unless it is side-mounted on a vertical metallic support, or has some other form of v-pol parasitic radiator near it.

And in that case, it's not your j-pole alone that is "beating" a yagi, but the combination of your j-pole and its mounting environment.

Put some ferrite tubes (big beads) on the coax near each antenna; this will
minimize radiation off the feedlines. Also, put a 3 dB attenuator on each
antenna, to stabilize the system impedance. Secure the feedlines so that
they are hanging in the exact same position each time. And don't forget that
40' off the ground is not good for frequencies below about 50 MHz.If you
want to dig very deep, there's an IEEE standard on antenna calibration (but
it's not free). You might find an old SAE 958 (IIRC) document on antenna
calibration.

sure it is. and while the 'static' field itself doesn't propagate the
leading edge of a step from 0 to some 'static' value can propagate and if
you measure as it passes you will see the received signal go from 0 to the
static value and then stay there.

Must be one horridly poor yagi. Most 3 eleemnt designs are better
than 8dBi and with a little effort an be 1 db better than that.

Most Stacked Jpoles do not perform as well as predicted on paper with
the upper added dipole contributing .5 to 1 db less than guessed at.

If I read this correctly, the more above ground radials (to a point),
the better. Until one gets to 8 radials, there is a significant drop

in antenna loss.

How do the gains/losses change when the radials are disproportionate? i.e., you have been working with essentially a 40 meter vertical with 40 meter radials. What if I were to place a 20 meter vertical (16 foot for example) on that 33 foot radial system vs placing a 20 meter vertical on the same 8 radials 16 foot long?

One of the things I would like to have for a multiband vertical is the separate elements using GAP technology or just using a common feed point as seen in some of the handbooks.

Thanks for all the info. I have a eznic and the ARRL version, but there is something that isn't registering with me when using it. Sometimes there are things I just can't seem to learn unless someone shows me what i am doing wrong or missing.

Thanks for the info. I am just doing this for personal information
more than professional. I will probably experiment with higher
frequency antennas such as 15-6 meters and then scale them to the
larger antennas as needed. I realize I won't learn much about the
TOA or other characteristics. It isn't for purely scientific research
as much as it is to get a measurement somewhere in the general
ballpark of the antenna.

You are correct about the ferrites, but I hadn't thought about the
attenuators. That sounds like a good idea too.

Thanks for your input.

You might try it. Use some for of balanced line to the plate.
Connect one side of the balanced line to the plate and leave the other
empty. If you find another piece of metal there such as a gutter or
vent pipe, you might consider connecting to it.

While a balanced antenna might be best, you may find that just the
copper plate works well. In the antenna handbook or ARRL handbook are
end-fed antennas where the balanced line only feeds on one side to the
antenna.

This may not be the perfect antenna, but there is no reason it
shouldn't at least work some. I have loaded up the screen door and
talked across the country. It wasn't my ideal antenna, but it was fun
to play with :)

Good luck.

Do you really need fiberglass? I lookled at a 6 foot piece of white plastic water pipe, and it is quite rigid. It had been used as an antenna mast. My piece is about 1-3/4 OD.

Hi OM,

This is absurd. Video is a modulation being carried on RF, no one
broadcasts baseband on anything but copper.

The equally absurd notion offered here originally of DC offset being
RECEIVED is another fanciful illusion. Any such measurement was
clearly an error of measurement or understanding.

Before calling this reality absurd, consider that a television station transmits a video signal in/on an RF channel. The demodulated video waveform in the TV receiver will be identical to the baseband video signal applied to the TV tx -- including its DC components (subject to any distortions along the transmission path).

If it wasn't ~ identical, a TV set could never "fade to black" when the original image did, and low-luminance colors such as blue, red, brown etc would be impossible to reproduce with their original chromaticity.

You mis-read. There is a DC component _required_ to convey the steady voltage values preceding and following the step pulse transition. He's not saying that the step pulse transition itself is comprised of "DC."

Hi OM,

OK, this is after the reality: what you offer is either absurd, or
non-nutritive didacticism.

Throw enough capacitance on the output of a detector and you will get
nothing but D.C. and never observe an average of zero. So What? The
forced presumption that you should is laughable. The original
question is so clouded with speculation that elbowing fantasy into a
response allows for any statement to qualify as an "authoritative
answer." Save this stuff for White House Social Security math -
mathbonics?

Yes, that will really help. ;-p

I'd add the picture I looked at appeared to have a metal mast mounting
a vertical oriented beam and my experience at VHF and up is that hurts
performance.

All the years of building and testing says, extroadinary claims are
simply that. It's interesting to check the CSVHF range tests of
antennas on real antennas seperate from their sometimes fanciful
claims.

2063. Good News! -- Jesus Christ Went To The Cross So You Can Go To Heaven

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-06 19:34:52 UTC
From: Good_News_For_You_All@yahoo.com
Message-ID: <1107718492.484540.97930@c13g2000cwb.googlegroups.com>
Source record: 82451

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

Have a great day!

you will of course note that i quoted the term 'static' to denote that it was indeed not static in the infinite sense of mathematics, but in the real sense of it being a constant value over some measured time period.

the other obvious thing you are missing is that DC is a frequency... and it does come out in the Fourier transform as a frequency of zero with some finite magnitude for any waveform who's average value is not zero. it does not even require that the waveform stay at some value forever, a short pulse going from 0v to 1v and back to 0v will have a DC component in its spectrum both mathematically and on any meter that can properly respond to it.

Hi Dave,

This is fine as an elaboration that grows beyond the horizon of the
question. But it really serves no purpose but to embroider a glaring
lack of facts.

>the other obvious thing you are missing is that DC is a frequency... and it
>does come out in the Fourier transform as a frequency of zero with some
>finite magnitude for any waveform who's average value is not zero. it does
>not even require that the waveform stay at some value forever, a short pulse
>going from 0v to 1v and back to 0v will have a DC component in its spectrum
>both mathematically and on any meter that can properly respond to it.

After having done a quite rigorous contract with HP deeply involved in
both the strict math and the mechanics of Fourier, I am well versed to
know how not all Fourier Transforms offer equal outcomes - especially
with, or without D.C. as a product.

Pure Fourier mandates a waveform constant throughout all time (from
its inception to its end) and is strictly one of those "thought
experiments" when it comes to transients - obviously. This has been,
and is the first issue that comes with its classic requirements
clashing with utility.

Practical Fourier mandates that you remove all D.C. components through
what is called "windowing" your data. You can choose not to and enjoy
all the artifacts of spurious behavior (like frequency folding,
frequency blurring, and false baselines) and translate those results
into blighted proofs too. With transients, practical Fourier
techniques mandate the presumption that they are periodic through all
time by literally forcing the data set (through extensive reworking)
to fit this requirement (which returns us to classic expectation).
Such reworking of original data demands that you make a choice: you
either discard amplitude accuracy for the sake of frequency accuracy,
or discard frequency accuracy for the sake of amplitude accuracy. The
irony of this choice is that you have already discard D.C. and its
appearance within the product of results is imbued with error. Need I
ask if you know how much error? Ignorance to what accuracy your
transforms bring reduce arguments to platitudes.

Simple, day to day, practical applications of Fourier discard these issues as trivialities immediately and offer no pretense of "accuracy" because you couldn't appreciate it anyway (unless the designer of an IIR or FIR was so incompetent as to be that obvious).

However, this goes beyond the pale to justify a glaring presumption "average signal magnitude not zero" with the trappings of Fourier. For one, absolutely no one knows what is meant by "impulsive wideband signal (500 - 2.5 GHz)." This is so extremely vague as to be supportable by a multitude of waveforms that have wildly different Fourier results. For instance, there is the classic impulse of physics, lightning, which is notoriously low in frequency content over the interval cited. Clearly such impulsions suffered are not from nature. But this begs forcing the nomenclature to fit the problem. There are other impulses like a gated sine wave (which obviously renders a zero average), or a swept sine wave (same obvious average), or a ramp wave, or a saw tooth wave, or a triangle wave, or chirp wave. The list of impulsive wideband signals is exhausting, but hardly accommodating to the same universal expectation.

If our correspondent, Galilea, cannot come to terms with responding to technical issues when seeking help, the growth of forced speculation creates its own illusory discussion that is best limited to idle conversation overheard in a ticket line waiting for a movie box office to open.

The 'nominal' 12 volts is the voltage of the 6 two volt cells of a typical
auto battery, during normal discharge.
That is two volts per cell.
To charge a typical lead/acid battery a voltage of about 2.3 volts per cell
is required.
Therefore 6 x 2.3 = 13.8 volts.
Controlling to 13.8 volts is the job that the 'voltage regulator' does in an
automobile. To avoid overcharging and/or ruining the auto battery.
Therefore equipment which is designed to operate on nominally 12 volts is
usually designed to operate over the range 13.8 volts down to the point
where that battery is just about flat, at anything less than 12 volts. (If
your battery reads less than say 11.8 volts it's either shot or fully
discharged; BTW voltage is not a good indicator of whether or how well a
battery is charged!).
Large administrations e.g. AT&T, 'float' their large expensive battery
installations at around 2.15 to 2.17 volts per cell to offset 'local
chemical action' which causes batteries to slowly lose their state of charge
over time. For example 6 x 2.16 = 12.96 volts. This ensures the batteries
are fully charged at the start of a power interruption.

2069. Wireless Weather Station and Grounding

Newsgroup: rec.radio.amateur.antenna

If I put a wireless weather station on the roof on a 6' mast on tripod, can I simply run a grounding wire down to an 8' copper grounding rod?

I'd run lower loss coax for the UHF/VHF than RG-213/U, e.g. LMR400, Belden 9913F, etc, unless the run was less than 25 feet or so, maybe 50ft. For HF thru 10m (or even 6m) though the RG-213 should be just fine. It may be cheaper though to just buy a spool of the low loss and use it for the HF too than to buy two types of coax.

Like the conduit/EMT idea (make'm BIG and run a couple). Also, now's the time to run a *dedicated* circuit to the shack for a 240V amp supply. if not needed, it could be connected to 120V instead and the receptacle changed, but power only a single outlet box w/ it so you can easily switch to 240 V (duplex vs single breaker and new recepticle).

Hallo.

I'm looking for a shortwave antenna which can be easy build on a 25
meter mast.
This antenna needs a resonant frequenty of +/- 6.7 mhz.
The reason wy i wanna build this antenna is that my wife's mother is
living in Sumatra Indonesia and workt a long time for the national
radio.
You can say she is a real radio freak and that's wy I pick up the plan
to start a radio station here from holland (europe)so she can here
here our dougther and my wife on here own shortwave radio.
I have allready design a final amp for this project and it will be
ready in about 9 month. It's a class A 4cx15000 exiter modulated Amp.
It will produce about 6KW. Now we need a good antenna which can
handle this kind of power and can put the signal into Indonesia and
the rest of the world.
I can build a 1/4 wave vertical but in my opinion the vertical opening
of this antenna will produce onely one skip. I need an antenna with a
wide fertical angle so it will deliver the signal all throu out the
country's at all time. (multy skip)
To produce the power is not so hard but when we start our transmitting
my grandmother have to here it. That will be so nice.
I'm sorry that my english is so bad to explane exactly what i need so
i hope somebody will understand it.

2072. Re: AM radio reception inside passenger planes?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-06 21:21:11 UTC
From: Terry <tsanford@nf.sympatico.ca>

Source record: 82462
Cross-posted to: rec.travel.air,rec.radio.amateur.antenna,sci.electronics.equipment

> If you stretch a string on a globe from London to Florida, it will show
> the 'great circle' route that's the shortest, and that should be your
> plane's path, barring storme, hurricanes, etc. You'll see that it comes
> really close to the eastern Canadian provinces.
>
In fact the Avalon Peninsuala in the most eastern part of the island portion
of the province of Newfoundland and Labrador, Canada, is a 'Way Point' for
many transatlantic flights headed to/from Europe.
Clear days Transatlantic flight con-trails, at 30,000 feet etc. can be seen
almost continuously.
That is why so many of the flights that were prevented from entering US air
space 9/11 had to land in eastern Canada.
Many US/Canada friendships were founded between grounded travellers that day
and eastern and western Canadians who voluntarily accommodated them during
the delay.
Cape Spear near St John's is the most easterly point in North America.
Marconi received the first transatlantic wireless telegraph signal near St
John's in Dec. 1901.
French is one of the 'Official Languages' in Canada. A significant
percentage of the population, mainly in Quebec, New Brunswick, but also
elsewhere in Canada, is French speaking. Many/most are bilingual.
Same way Spanish is significant in the USA?
The word 'Cajun' in southern US comes from the French word "Acadian";
originally inhabitants of Acadia or what is now the eastern Canadian
Province of Nova Scotia.
Terry.
PS. Staff at the National Historic Park at Signal Hill, St. John's, which
incorporates the memorial and events which celebrate Marconi's first
wireless telegraph reception say that visitors unaware of the approximately
1800 miles across the Atlantic, (4.3 hours by jet to London-Heathrow) will
sometimes ask "Can you see across to England/Ireland etc.". The answer is;
"No, but sometimes you can see "Whales"! :-)
And sometimes icebergs as well.

Your rhetoric is evasive and blustery -- no doubt so you won't have to admit publicly to an incomplete understanding of what you are responding to.

Enjoyed this thread. It elevated the word 'aerial' to new heights!
Noting also that during it, no one, as a previous English teacher of mine used to say, "Demonstrated their inability to express themselves properly by descending into profanity".
The same teacher, however, also claimed, "Anyone using words such as 'sox' and 'foto' were definitely not using the English language"!
In the 1950s Broadway show 'My fair lady' based on G.B.Shaw's Pygmalion, there is the line, "There even are places where Engish completely disappears. In America they haven't used it for years!". It was good for a laugh.
Personally; if we can combine the American skill for inventing/designing/adapting words so that so that they are terse and descriptive with the British penchant for contrasting and 'punning' the various meanings of words, we will continue to have a rich and adaptive language which will, as from the time of Chaucer and Shakespeare, be the most powerful communicating language in the world. More power to us.
Terry.

2078. Good News! -- Jesus Christ Went To The Cross So You Can Go To Heaven

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-06 22:00:17 UTC
From: Good_News_For_You_All@yahoo.com
Message-ID: <1107727217.550681.295620@l41g2000cwc.googlegroups.com>
Source record: 82467

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

Have a great day!

How did you come to this conclusion? What
sort of field strength equipment did you use?

Again, i would be the first to say
that reality doesn't fit the math model,
sometimes not at all. But is this case,
you can really hear the difference.

Surely as a former broadcast engineer you're acquainted with a circuit called a "DC restorer". This is a circuit which is always present in a TV receiver. In its simplest form, it's just a diode clamping circuit, although I've made very good ones with an FET switch and hold capacitor. What it does is to set the sync pulse tip to a fixed DC value, which then causes the rest of the TV waveform to be at a fixed DC value. This is how the DC information is "transmitted". The actual TV waveform is AC coupled, as it must be, and its DC values are established in the receiver by the DC restorer.

No DC value is transmitted.

You should be able to find an explanation of this in any basic text on the principles of television transmission and reception.

You perhaps never installed a receiver. Without its DC restorer circuit, the problems you mention do indeed exist. In a black-and-white set, a large white area will cause everything else to go black, to maintain a zero average. But the DC information is transmitted as a level difference between the sync tip and the "porches". At the receiver (as I mentioned in another post), this voltage *difference* is turned into a DC value. No DC is transmitted.

Surely a little bit of thought will establish why direct transmission of DC isn't possible beyond the range of a static field.

Nope, you didn't. My analysis was for buried, not above ground, radials. And the loss increases, rather than drops, as the number increases. This has been well known since at least 1937.

> How do the gains/losses change when the radials are disproportionate?

There are an infinite number of such questions, each with its own answer. But a little research will show that the difference between 16 and 33 foot radials will make little difference on either 40 or 20 meters. There's been a lot posted on this newsgroup in the past about ground radial systems -- you'll find the answers to many of your questions by using groups.google.com for a search.

>
> One of the things I would like to have for a multiband vertical is the

> point as seen in some of the handbooks.

You really want to use a lossy piece of coax to load your antenna as the GAP does instead of a more efficient method? Why? Fanned wires with a common feed point will be more efficient. If you bury the radials, you need only one ground system -- 8 or so radials will get you within a couple of dB of a perfect system.

I must respectfully disagree with that, Sir. The baseband video signal is *
DC coupled * through analog TV transmitters . The peak power of a
transmitted TV RF waveform is a fixed value, at the power corresponding to
the licensed ERP of the station, occurring at the peak of sync pulses, and
independent of program video. Transmitted _average_ power is a function of
the video envelope.

Video is transmitted with negative polarity; 75% modulation when video is
black, and 12-1/2% modulation when it is white. The video waveform AS
TRANSMITTED can contain a steady state (DC) value throughout the video field
for any amplitude at or between those values (actually the color subcarrier
can exceed these for some conditions).

The circuits in a TV receiver cannot pass the DC component, thus the need
for a DC restorer following the video demodulator. But the point remains
that the transmitted TV waveform can, and often does contain a DC component,
and that this DC component is required for accurate reproduction of the
original video on the TV display.

RF

PS: I still AM a broadcast engineer.

As I wrote in my slightly earlier post to you on this, the actual video waveform is DC coupled through an analog TV transmitter. Please refer to that post for more on this topic.

> How did you come to this conclusion? What
>sort of field strength equipment did you use?

Simple testing with a stable RF power source and a sensitive field strength meter in a very large yard. It's not hard to determine a 1Db difference and a 3db one is easy.

The other is a colinear design the second element cannot contribute 3db unless the first didn''t radiate any energy. Thats rarely the case. To get the gain you claim try a 8 or more segment colinear and note that would be about 18-20ft tall for a 2m antenna.

> Again, i would be the first to say
>that reality doesn't fit the math model,
>sometimes not at all. But is this case,
>you can really hear the difference.

Usually the math model is reality if its a real model. Often it's not. manyy of the simple shorthand models are far for accurate or complete. Also in some locations there are third order factors not considered. For a real model (NEC based) the stacked Jpole is 2.3->2.4dbi better than a plain J and ends up at about 7.4Dbi. [In real terms that's only about 2.4 DB better than a vertical dipole which a basic Jpole is.] That gain (7.4 DBI) is easy to beat with a 3 element beams on 2m (typical is 8dbi) though a simpler half square is 9.4dbi. Having built many antennas and examples of the three mentioned I find the models are accurate. However, if you cannot measure and test the antenna effectively you cannot evaluate if it's working as predicted or if its working at all. At VHF execution is everything and subbing 1/4 inch tube for a modeled 1/2 inch one will give error, sometimes significant. I'd add that at VHF the feed section is critical and if not done well the rest of the antenna is a waste of metal. The Jpole in this case is easier to evaluate because if the SWR is poor it's definately not working well and a lot of things have to be correct or the SWR will be poor.

For example, it may work better because its nearly 60inches taller and at a given location that could be the majik. Never ignore height as a significant factor at VHF.

If you care to read www.cebik.com/jp1.html all four sections. It's an indepth treatize and explanation of J-poles and varients. Based on my experience he's hit the nail accurately.

Oh, and I use two Jpoles (arrow OSJ146/440 and a Copper cactus
for 2m/440) and both match the model for performance in the real
world. Obviously I'm neither pro Jpole designs nor am I against them.
They work well to the designs limit if built carefully. I like them
for the ease of assembly of a rugged design that's reproduceable.

Allison

After looking at the picture and the plot I fired up yo
and the only way I could get that low a gain was to
seriously mess up the antenna. The end effect was
a 2 element yagi witha spurious useless element.

This is further confirmed by the picture. It appears
the rightmost element is the fed element (very strange for a three
element design) and the proportions suggest a reflector close to the
driven and longer. The third element (the leftmost) would be spurious
as it's behind the reflector and far away.

Please explain that yagi, it's strange.

According to most of what i have read,
every doubling of the sections give approximately
3 dB additional gain.

I used a program called Yagi Optimizer.

It should be close, it's not like
we are modeling active devices like FETs
and such!

> Also in some locations there are third order factors not considered.

Incorrect. A stacked J-pole cannot
be 2.4 dBi better than a plain J. It can only
be 2.4 dB better.

Anyways, You think a plain J-pole is 5 dBi?

Incorrect.

The

Obviously. They are at about the same height,
considering the additional height of the Super J.

I would say that at VHF, a Super J is a
bit heavy and big, but the additional ERP
is worth it.

I have it all sorted out. The 2002 ARRL Handbook has a similar table complete with voltages. However, there was a mistake in the text. Working backwards from the stated result, we found the text used a coil capacitance value of 2.5 pF while stating they we using 2 pF. They also assume Rg (ground) is zero. I can duplicate their table and have calculated the data I was after for the other whip lengths.

I have a .xls spreadsheet I can email anyone who is interested.

It was an unusual use of the YO
program, in that we used two reflectors
and NO directors, to get the shape we
wanted. We actually couldn't use the
optimizer, because it would actually
try to narrow the beam too much.
Remember that you must keep the
pattern about 180 degrees, and the F/B
ratio should be no more than about 11 dB.

If you could come up with something with
a higher overall dBi, i'd like to know,
but i doubt it.

Thanks for the correction. As a Novice I learned that underground
radials were better than above ground radials. I couldn't be sure
which you were using so I re-iterated it to be sure.

>> How do the gains/losses change when the radials are disproportionate?

I didn't clarify myself, but the gap technology (I should have used
lower case) isn't necessarily the same as the GAP brand. I couldn't
find the book I have it in, but it is where a wire resonant on a
particular frequency brought close to another antenna will match the
system and radiate efficiently (I don't know how efficiently.) (this
is an oversimplification of what I am describing.)

>I've heard many good comments about the ARRL on-line course in antenna
>modeling. You might consider it.
I'll look into it. I understand a lot of what I am doing, but
something isn't working. I think it is one of those things that
someone needs to walk me through one time looking over my shoulder and
I'll get through it. Maybe it will just come to me one day.
Sometimes these things happen.

Thanks again.

Slick,
Could you explain the use of two reflectors? I've heard that if you are building a two element yagi it's best to use a radiator and reflector but haven't really learned anything about using more than one reflector. Have seen antennas that use 3 reflectors, but they were mounted perpendicular to the plane of the elements and there were several director elements - if memory serves me it was Cushcraft that did that. Haven't seen them added behind the first reflector and am curious as to what characteristic of the antenna's performance it is meant to enhance.

Thanks,
Howard

For this particular design, it was
required in that we needed something with a
180 degree pattern, and not to much F/B
ratio. I can't tell you much more other
than we had to manually tweak the variables
to get a decent result...we couldn't use the
program's optimizer, it would have made the
forward lobe too small.

So what ends up happening in the program,
is that you end up using two directors, but
in the H-plane the lobe goes to the rear (see

link). So in essence, you flip the whole deal around, and your two directors are actually reflectors. Interesting, eh?

Hi all...I am preparing to mount an Alinco DX-70 transciever in my 2003 Merc Sable and have found a spot underneath the body next to the frame rails on the rear passenger side of the vehicle to mount an EDX2 tuner....this will give me a very short piece of wire needed to attach to the base of a vertical antenna.
I am a bit leary of exposing the tuner, despite the case being in very good condition, to the extreem environment underneath the vehicle...
Any suggestions as to a material to wrap the tuner in??
I guess I could make a platform next to the vertical antenna to attach the tuner, but would like to try the underbody method first.

That sounds like the method patented in 1996 by Gary Breed, K9AY (U.S. patent #5,489,914). He allowed the patent to expire rather than renewing it, so it's now in the public domain.

See http://patft.uspto.gov/netacgi/nph-Parser?Sect1=PTO2&Sect2=HITOFF&p=1&u=/netahtml/search-bool.html&r=1&f=G&l=50&co1=AND&d=ptxt&s1=gary.INZZ.&s2=breed.INZZ.&OS=IN/gary+AND+IN/breed&RS=IN/gary+AND+IN/breed

(You'll probably have to paste that back together. Or just go to http://www.uspto.gov and look it up by patent number.)

This has me confused...I must be missing something...I checked the
previous
posts, but still doesn't make sense to me...Seems the ground losses
would
decrease as the number of radials increase....Thats what your model
showed.
I thought anyway....
> >
>
> Thanks for the correction. As a Novice I learned that underground
> radials were better than above ground radials. I couldn't be sure
> which you were using so I re-iterated it to be sure.

For a given radial, above ground is better than in ground. But it has
to
be resonant. In that case, you are running a very low ground plane.
If it's just one radial, it should radiate as much as the vertical
element. In that case, it's more of a perverted dipole, than a ground
plane. A true ground plane really needs at least two radials to get a
fairly unlopsided omni pattern. Three radials are better.
If you use 120 radials on medium ground as a benchmark, any height
above
ground will reduce the number of radials required to equal the same
degree of loss. But once the radials are elevated, they must be tuned.
Radials on or in the ground do not need to be resonant.
If you ran a vertical, and can only use a very few radials, having them
tuned and a bit off the ground is better than the same in the ground.
Of course, the YL will probably want to strangle you with one, the
first
time she trips over one...But some run them around the lower frames of
houses, wood fences, etc...
One thing....It's not a magic wand to suddenly make low 4 radials a dx
buster...At 1/8 wave up, it takes appx 60 radials to equal 120 on the
ground. On 40m, thats 16 ft or so... At 2 ft off the ground, you still
probably need maybe 90? radials to equal the 120 on the ground.

So you have to consider that, when you run 4 radials at 2 ft, and don't brown the food in every direction. It is a bit better than 4 in the ground though, and Roy's model pretty much agreed...I think anyway...:/

You are lucky to see the gain you have, considering the lack
of decoupling...Or at least in that pix....Also, thats a
pretty lame yagi, so like you say, not really a fair test...
My 3 el vertical yagi would eat that j pole for lunch, being
it has about 9.4 dbi gain...Or about 7.3 dbd....
The J poles are ok I suppose, and are good for people with
copper and torches...But they would be even better with some
additional decoupling...I bet they still have trouble matching
the old isopole that was made by AEA...That antenna was well
decoupled. Looked like a ballistic missile, but it was hard
to beat as far as performance. It was generally the benchmark
most other dual 5/8 designs were judged by.

Roy, it is a mistake to consider one element of a radiating system as being distinct from another. Reflectors and directors do not operate independently of the embedded 1/2-wave dipole. And, for example, the universally-made error of treating radiation from the feedline as being independent of that from the antenna is a serious matter. Aggravated by ignoring the choke location if there is one.

Similar (greatly prolonged) educational mistakes lead to serious misunderstanding the purpose of the so-called SWR meter - the very last of the meters remaining on the front panels of our commercial black-box transmitters.

They will soon go.

But what does it matter. It's only a hobby. I still get my pleasures from it. And no doubt so do you.

What lack of decoupling? It's got the
coax inductive choke on the input, 4 turns
of 4" diameter.

If you would read my posts more carefully,
you would be aware that the reason for the low
dBi is that the lobe is 180 degrees, and F/B
ratio limited to around 11dB.

> My 3 el vertical yagi would eat that j pole for lunch, being
> it has about 9.4 dbi gain...Or about 7.3 dbd....

So what, the Super J-pole in omnidirectional,
so that's not saying much for a Yagi. We could have
easily designed it with more gain, but the frontal
lobe would have been way narrower.

How broad or narrow is the front lobe
of your yagi? How many degrees? Much
smaller than 180 no doubt.

What lack of decoupling? It's got the
coax inductive choke on the input, 4 turns
of 4" diameter.

If you would read my posts more carefully,
you would be aware that the reason for the low
dBi is that the lobe is 180 degrees, and F/B
ratio limited to around 11dB.

> My 3 el vertical yagi would eat that j pole for lunch, being
> it has about 9.4 dbi gain...Or about 7.3 dbd....

So what, the Super J-pole in omnidirectional,
so that's not saying much for a Yagi. We could have
easily designed it with more gain, but the frontal
lobe would have been way narrower.

How broad or narrow is the front lobe
of your yagi? How many degrees? Much
smaller than 180 no doubt.

Yes - if you like; I was alluding to curvature in the transfer
function as non-linearity, which one would encounter before
clipping.

"Roy Lewallen" wrote about broadcast television waveforms:
> ... No DC value is transmitted....
and
>...The actual TV waveform is AC coupled, as it must be, and its
>DC values are established in the receiver by the DC restorer...

Please think about this. Standard TV color bars are produced by mixing the outputs of three video pulse generators. The pulses are square waves, with amplitude limits of 0 and 0.7VDC (~0.25ï¿½s transitions). These three video waveforms are shown in Figure 7-1 in the paper hyperlinked at the bottom of this post.

The DC present during the "on" time of these video pulses is indistinguishable from the DC supplied by a continuous 0.7VDC source, over the same, steady-state time interval. The DC and near-DC values of this video must be available to the TV display device in order to accurately show the color bar signal (and any other video waveform).

Low frequency content is lost when video is AC-coupled through a TV transmitter (or any other circuit). A TV set DC restorer sets and maintains the DC axis on which the pulse rides, but that does not correct the distortion of the pulse waveform resulting from loss of its low frequency content near zero hertz (DC).

Also recall that even the shortest pulse* that can pass undistorted through the ~4MHz video bandwidth of the US broadcast TV standard contains most of its energy at, and near zero hertz, e.g., DC.

*a sinï¿½ pulse with 0.25ï¿½s transitions

So DC _is_ , and must be conveyed by analog broadcast (and other) television systems, because television wouldn't work well otherwise. It isn't DC as you may think of it coming out of a battery, but it is DC, nevertheless, and identical to battery DC of the same amplitude, when compared over equal, steady-state intervals.

Perhaps the measured DC value is not the result of EM waves
but the result of mechanical depositing of charge on the
antenna. I assume that wind/snow static is DC - enough DC
to cause arcing across a coax connector.

I didn't catch this either. I misunderstood it to be that the number
of radials decrease loss. However, I do well remember that the
preferred radial of the day when I was first licensed was below ground
radials. Today I see a lot of antennas preferring above ground
radials.

Richard,

Sorry about the triple. I was so caught up in the excitement (constant throughout all time) of your message I just couldn't stop.

Quote:

"After having done a quite rigorous contract with HP deeply involved in both the strict math and the mechanics of Fourier, I am well versed to know how not all Fourier Transforms offer equal outcomes - especially with, or without D.C. as a product.

Pure Fourier mandates a waveform constant throughout all time (from its inception to its end)"

I can ignore the name-dropping, but I cannot ignore the incorrect statement about "Pure Fourier". There is no mandate of constancy even for the purest Fourier transform. The function needs only to be moderately well-behaved, including single valued and integrable.

Perhaps you are confusing Fourier series analysis with Fourier transform analysis?

(By the way, for any of the lurkers out there, I did not say a word about "DC". That is a trivial matter subject only to one's choice of wording. There is no apparent disagreement on the reality, only the description.)

73,
Gene

There have been a number of changes in technology theory in the last
30 or so years. When I was a Novice, the vertical antenna
manufacturers provided information about how to use above-ground
radials, but that was typically for a raised antenna such as roof
mounting it. IIRC, the above ground Hustler 4BTV and the Taylor
antennas both had to be lengthened a little to be resonant in the same
place as the ground mount and radials had to be tuned. Reports at
that time were that antenna efficiency was best when the antenna was
ground mounted and had 8-16 radials buried. However, while not
optimum, the minimum ground was to be an 8-foot ground rod at the base
of the antenna. Baluns seemed to be a new technology, I don't recall
the term "ferrite beads", and RF in the shack wasn't a big issue. One
common practice was having a ground rod as close to your rig as
possible and making sure the rig, PS, antenna and everything
electrical near the rig was grounded to the ground rod. Today the
electrical code for homes forbids that due to ground-loops.

Some of these changes take some getting used to. It's a strange
feeling to realize that what you knew for so long is no longer true.

|Thank you in advance for your comment

What is in blue is correct. Your answer is not.

Once you have the cummulative noise factor and gain for the
amplifier/output filter it becomes the second stage for the
calculation of the input filter/amp cascade.

Note that the *gain* of the first stage (filter) is -2 dB (0.63)

Noise factor = 1.58 + ((3.548 - 1) / 0.63 = 5.62

NF = 10 log(5.62) = 7.5 dB.

Try this calculator:

http://www.marsport.demon.co.uk/tcalcxl.htm

I have a multi-band dipole, similar to the fan-dipole. A couple of
weeks ago the rain coated my antenna and bridged the gap between
center and shield on my coax. My antenna went from matching 80, 40
and 20 to matching 12 and 17. This was short lived, but it lasted
long enough for my friend and I to get a good laugh.

Typically, without the ice, the weather shifts the center of resonance
on my antennas. Sometimes it kills the use of a band or in case of 80
meters, it shifts from the SSB to CW (or visa versa).

I threw this antenna up in a hurry and added to it off and on over
time. It was supposed to be temporary so I didn't use a balun or
weatherproof the so-called cobra-head, which is really only a piece of
PVC with three holes drilled in it and the center to one wire and the
coax to the other.

I also have a properly built 20 meter antenna where I ran the coax
into a PVC t-connector and the wires connect at points several inches
away so there is no water bridge and the coax stays dry.

Hi Gene,

In this case you are seriously wrong. There are no IFs ANDs or BUTs.
The loop hole of well-behaved is not enough with it being far too
inspecific.

The ONLY case where the Fourier Series resolves a correct
transformation is if you limit your data set (or for an Integration,
you define your limits) over an interval of n ï¿½ 2 ï¿½ PI for a periodic
function where n is an integer from 1..m. Further, you are resolution
limited if you fail to observe Nyquist's laws and under sample, or
fail to frequency limit your real data. This also segues into
Shannon's laws where you can observe the S+N/N in the transform
(discussed below). These concerns are EXTERNAL to the simple act of
transforming data, but are necessary correlatives that MUST be taken
into account.

If you fail even in this simple regard for periodicity (say looking at
only 359 degrees of the periodic function), the result is quite
dramatically different in the Fourier output. Even the casual
observer can immediately see the difference between the correct and
incorrect results, there is nothing ambiguous about it at all.

>Perhaps you are confusing Fourier series analysis with Fourier transform
>analysis?

No, I have done both, and I will drop the name again, at HP with their
work on Fourier Analysis equipment where I tested their FFT algorithms
(call them what you may, the basic underlying requirements do not
change). I was working with 24 Mathematicians AND Engineers - there
was nothing sloppy about the quality of up-front preparation. This
was a project 5 years in the making. They even wrote their own Pascal
compiler for 1000000 lines of code. I have also done IIRs and FIRs,
Wavelets, and a host of other frequency/time series decimation
analysis.

ALL Fourier techniques have requirements that go beyond the Fourier
math. These requirements (if you have any interest in accuracy)
cannot be ignored. If you have no interest in accuracy, you still

have to perform some of them, which is to say there are trade offs as I mentioned previously. Ignoring them all simply reduces real data into transformed garbage.

I have written FFT software that has resolved pure sine waves into a transformation to a single bin with a statistical noise floor and ALL spurious response down 200dB. To give an example of what 1ï¿½ of decimation error will do, it will inject 120dB of noise into the product and spurs that are barely 10 to 20 dB down from the principle bin (which also exhibits about 3dB error).

Much of what is available through college texts and on the web are seriously under powered in their scope. College is not very interested in scope, simply introduction. That is, unless you find yourself in a undergrad (more probably grad school with the additional considerations taken into account) engineering course dedicated to modern implementations (practical Fourier) now largely focused on DSP (which had its genesis in the IIR and FIR earlier implementations).

Dr. Slick wrote;
"Well, our super J-pole is bearing our yagi in ALL directions, even in the forward lobe."

It`s possible.

This thread pits a "Super J-Pole" with 6 dBd gain against a "Yagi-Uda" with 2.85 to 17.85 dBd gain (5 to 20 dBi), depending on construction. So, it could be true for some 2-element Yagi or it could untrue for a Yagi with 3 or more elements. A 3-element Yagi may give about 5 or 6 dBd gain.

The "ARRL Antenna Book" gives the details. In my 19th edition, the Super J-Pole is asid to give 6 dB gain over a 1/4-wave whip on page 16-27.

The whip with a perfect reflection (a ground-plane antenna) is said on page 13-10 to be equivalent to a 1/2-wave dipole in free-space: "---the image of a vertical antenna is in phase with the vertical radiator". The whip with the perfect reflection is thus identical to a 1/2-wave in free-space in performance. Gain of the ground-plane is 0 dBd or +2.15 dBi.

Best regards, Richard Harrison, KB5WZI

2141. mast as yagi reflector

Newsgroup: rec.radio.amateur.antenna

Can a grounded metal mast ever be useful as a yagi reflector?
http://www.qsl.net/dk7zb/2m_veryshort/2ele.htm
apparently uses a metal mast as a sort of reflector.

If the mast is "very much longer" and "very much thicker" than the
other elements, does its distance from the other elements "stabilize"
in the design and not keep changing as we change the other factors.

Maybe this might be useful in making 'foolproof' 3rd world yagis,
where the user merely owns a tape measure and various metal rods. He
already has a reflector much thicker than the 50 ohm split dipole
driven element, so maybe thickness and metal type of the latter
wouldn't be that critical, as at least he could clip it to the right
size (=what?) for 144-146 MHz? Presto, he has a 2 element yagi?

Matters if he has stuck his mast right into the ground, so it is more
or less grounded or not?

This only raises the obvious cynicism of choice. You could have
selected a worse antenna to claim a better contrast - there are always
losers available for use as a cat's paw.

For an honest comparison, it is sufficient to simply report your
characteristics in units of dBi and offer the angle of measurement.

Speaking of reports, your breathless testimonials draped with the
mantle of
are described in less than specific details:
>So if you assume
...
>So we have about
...
>That's like
...
>That's like
...
> It's only a theoretical
...
>we didn't really
...
> It's still not really a fair comparison.

All of the above don't really mean much, because no real details of
anything are actually revealed. So when we get to this:
> I presented the theoretical calculations, not actual measurements, sure.
I would say without fear of any real contradiction that NO you did
neither.

And then to rely on the customer to confirm by
>you can really hear the difference.
is droll indeed. This the same effete standard of wine snobs who
justify paying $300 a bottle for Chateau Annie Green Springs. Let the
bottle caps fly!

It takes no great effort to duplicate your rather sloppy presentation
to offer many better, smaller designs that eclipse your speculated

results. Through selective disclosure, choosing a weak competitor, leaning on abused references, and one thumb on the scale, anyone can inflate performance claims to satisfy a customer (or attract more).

However, when one pirate fleeces a community of pirates, I can enjoy the cluster**** going on and offer "yo-ho-ho, and a bottle of rum!" It is a comedy of a genetic self-thinning population after all.

HighSierra makes one optimized for base operation. In
general, a base station is not usually limited to 13.5
ft. as is a mobile, and any addition to the length of
a very short antenna is an improvement.

>A DC short circuit but not a RF short circuit?
>Or is it just salt water that is worrisome?

Hi Dan,

Water is an insulator, and a very good dielectric. It would make for
a very good method for building high valued capacitors (displacing
inferior oil), but for one remarkably aggressive characteristic.

Water will disassociate many things (act as a solvent or simply as a
transport). As such it quickly degrades its dielectric characteristic
when in contact with nature. If you were to insert two probes to
measure its initial conductivity (presuming you start with distilled,
de-ionized water), you would find it easily in the megOhms if you
could measure that high in the first place. However, the simple
immersion of the probes (depending on their material and time
immersed) will lead to increasing that conductivity - such is the
aggressive nature of water. Nature is rarely that pristine, so to
dwell on de-ionized rain offers its own comedy of failed expectation.

So, that is the long way of saying you are on the greasy skids of
seeking an all-inclusive answer except to simply offer: don't trust
one. Decades of experience, however, yield practical answers. Look
at insulator materials and construction geometries. Largely, these
two are well tailored to shed water and increase surface area for a
fixed length. If you are worried about salt water, visit a marine
supplier who sells electrical/RF equipment (hard to imagine they would
by shy of examples). These rather simple items reveal how few find
water worrisome after their installation.

Now, if you want the warm snuggly feeling of data to two or three
places, the theory to back it up, and allusions to wave mechanics (be
they water or RF). Time and space will enlarge in this forum to allow
that easily.

2147. GP -> yagi driven element?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-07 19:28:26 UTC
From: Dan Jacobson <jidanni@jidanni.org>
Message-ID: <87k6pkgof9.fsf@jidanni.org>
Source record: 82248

Having failed with yagi recipes, too fancy for rudimentary non meter owner me, I shall now restore my GP antenna, the one with three spikes at bottom, and six spikes at its waist.

But why not place it in front of, not atop the 2 inch diameter iron pipe mast where it sat, and in front of them place a 3rd pole? Voila, a 3 element yagi to boost 145 MHz transmission to the big city 15 km away perhaps.

Wait, the GP is much longer than any yagi recipe's driven element for 2 meters. Well, so is the mast much longer than any recipe's reflector...

And all yagi recipes have elements grounded at the middle, if at all, whereas my reflector and director would be grounded at their bottoms, unless I place an extra wire...

Hi Jimbo,

You need only to consider that in your base application, you need as much linear/mass equivalency to a truck/car frame to reproduce the same results. It has been long observed that these highly specialized antennas are in fact a tuned ground/counterpoise/radial in comparison to the larger radiating surfaces of a truck or car.

If you think of them in these terms, you can allow invention and available structures to solve more problems when you bolt one of these to them.

it's true. But this doesn't mean that
it's going to beat ALL Yagis, which
is what some people have thought this
thread was all about. Just THIS 180
degree Yagi, with 11 dB F/B ratio.

> This thread pits a "Super J-Pole" with 6 dBd gain against a
"Yagi-Uda"
> with 2.85 to 17.85 dBd gain (5 to 20 dBi), depending on construction.

6 dBd would be about 8.15 dBi, which is not
the case here.

The Super J-pole is 5.5 dBi or 3.35 dBd.

This particular Yagi is about 4.5 dBi
in the front lobe, which was a compromise
to get the 180 degree pattern (and 11dB F/B).

>
> The "ARRL Antenna Book" gives the details. In my 19th edition, the

Really? If we say the 1/4 wave is 2.15 dBi, then
the Super J is 3.35dBd, omni.

So i'm not sure where they got these numbers,
or if we are talking about the same thing.

Source record: 82240

The short answer is that water won't cause any problem, and even salt water probably won't (except corrosion).

When water bridges across a driven element or to the boom (not by any means the same as the Earth), you've put a high value resistor and capacitor across the driven element or from the element to the boom. Pure water is a good insulator but acts also like a lossy capacitor at RF; rain water on an antenna will have some dissolved minerals so that reduces the shunt R. The feedpoint impedance of a beam is quite low, so all you've done is put a high value of impedance across a low value. The change is therefore very small. This holds for half wave dipoles, quarter wave verticals, and most other common antennas, too.

A few antenna types have high impedances at the feedpoint, like an electrically short whip, or a full wavelength dipole. Although I don't know of any rigorous tests, I don't think even these are commonly bothered much by water.

Oh, ok, so you thought i was making some
sort of grand statement that a Super J will
beat a Yagi regardless of the design. That's
not what i'm saying at all.

With THIS PARTICULAR 180 degree yagi,
the Super J beats it in all directions.

Really i should have just made the thread title, "Observations on the Super J-pole and Wide angle Yagis in the VHF broadcast band".

If someone can come up with a 3 element yagi (we wanted to keep the size down), with a 180 degree front lobe, and about 11 dB F/B ratio, that has a better than 4.5 dBi in the front lobe, i'd like to see it. Use EZNEC or whatever simulator you have, and make an H-plane plot... i'd like to see that.

The reason we wanted 11dB F/B ratio, is that for this particular usage, it was NOT on the edge of town, and so we still wanted to have enough ERP to the back side.

A good receiver actually gives you
TONS of information. You can hear overmodulation,
sideband "splatter" to adjacent channels,
spurious oscillations on other channels,
dead carrier hum in your signal, the overall
intelligibility of your signal and the audio frequency
response (roughly). No field strength meter can
tell you this information!

Bottom line is, human hearing is
the ultimate destination. It can
be more qualitative that quantity.

I challenge anyone else to use
whatever Yagi Optimizers they have
to come up with a 3 element design
(to keep the size down) with a 180 degree
front lobe, and with an 11dB F/B ratio,
that has a greater than 4.5 dBi in the
front lobe. Plot the H-plane of your
simulation too.

The most common problem is if water gets into the traps (if your horizontal antenna has them)

Some traps have drain holes and they should be oriented so the drain hole is downwards

A friend had them upwards and the SWR would go way out of sight when it rained, so he was off the air until the traps dried out.

We changed them, no problems even in a downpour

I just received a gift of 10 silver plated body/gold plated pin/Teflon dielectric PL-259's made by J&I. I normally use Amphenol 83-1SP's for all my PL-259 needs. I was just wondering if there's be any dissimilar metal corrosion if I used these with non-gold plated receptacle SO-239's?

Funny thing is...upon looking at some of the SO-239's on my rigs, tuners, etc., some of them actually sport the gold plated receptacle SO-239. I'd never even thought to look before, hi.

Any comment re. any experiences w/J&I PL-259's would be greatly appreciated. Tnx in advance es...

This is a hollow challenge in that such designs are already freely available through EZNEC. Again, the thumb on the scale scenario offers easy ways to pencil whip these numbers above, given they are only partial disclosures tricked up for the benefit of marketing to suckers otherwise inflating their egos as "pirates."

To that band of would-be broadcasters, it is patently obvious that our salesman here has already admitted that no Yagi Optimizer was fully engaged to optimize the "3 element design." (And there is an absolute lack of data for this so-called Super JPole.) As such, he is mocking your credulity to suggest that YO would somehow be appropriate as a package to pursue this particular goal. When marketing has such contempt for customers, you have to wonder about them (both marketing AND the customers).

What is even more contemptible, is the notion that the inferior design is preferable to other designs (they abound for that very reason). The suggestion of any superiority of the "super JPole" has already been draped in presumptions and strained references. This is simply the clouded judgment of a solution in search of a problem. When all you know is about JPoles (which is arguable), then they solve all of life's transmission woes.

Much of this tarted up comparison smacks of a quarter mile race between a corvette and a school bus - ignoring that you wanted a recommendation for a bicycle.

I will leave it to the more industrious customers or would-be customers to simply download the free version of EZNEC and confirm that this clod-hopping 3 element design above would be bettered by a 2 element one. This has already been offered by Allison to no noticeable intelligent response. I will leave it to those who glom onto vacuous marketing with the fatal attraction of a moth for a flame to skip this exercise.

To some extent, yes... or at least so I've been lead to understand.

A local repeater committee I'm part of has been discussing the idea of replacing our existing Hustler G7 omni with a commercial antenna which uses a stacked set of half-wave folded dipoles. The dipoles are normally side-mounted from a metal mast, held out at a distance of somewhere around 1/10 wavelength.

The antenna designer at the factory told us that we could choose from any of several different sensitivity patterns, ranging from a near-cardioid pattern, to an "off-center circular" (something looking fairly close to what an omnidirectional pattern would look like if you were to "push" it 2-3 dB to one side, if that makes sense).

The principal difference between the antenna designs for these patterns, is how close to the mast the folded dipoles are placed. In effect, the mast is acting as a non-tuned reflector, creating more or less of a dip or null in the antenna's pattern in the direction of the mast, and a corresponding boost to the pattern out on the opposite side.

My impression is that it's difficult to get a deep back-side notch or null with this sort of arrangement... the front-to-back ratio is low. It's a useful way to shape the pattern of an otherwise-omnidirectional antenna to cover a not-entirely-circular service area. I don't think it's likely to be all that useful for applications needing a substantially directional pattern, or large front-to-back ratios.

For the sorts of applications you're speaking of (easy and near-foolproof Yagis made with simple materials under Third World conditions), the classic "Cheap Yagi" design by Kent Britain WA5VJB

seems idea. They're easy to construct, don't require a split driven element or a Gamma match or balun, seem to be non-critical in their design, and seem to measure out quite well.

I added an "s" by error. Sheesh.

I figured you'd know their products as they are well known in
broadcast and VHF/UHF ham circles. However that was only one example.
There is also CellOne who also do antenna products and other useful
items. Of course there are only a few hundred (or more) companies
making antennas many of which are suited for a cartiod pattern work.

>Thanks for any advice, jimbo

I don't have experience with them base or mobile except to have been on a trip with someone who has one on his truck. The antenna is great. If you must have a compromise antenna, putting one of these on the roof, maybe with the coil disguised in what looks like a vent, might be a great antenna.

As I understand it, you will want to use as many tuned radials around the antenna as you can get away with, at least two per band (four if possible) for maximum signal. However, if that isn't possible, you may consider grounding it to a large metal surface that surrounds the antenna.

I don't know of an efficient way to hide one in a tree, but someone here might have an idea that will be useful. Since it tunes itself, you won't need a tuner and 50 ohm coax will be sufficient.

Chances are you will need to add some form of one-to-one balun (UNUN) or hang a suitable number of ferrite beads on the coax next to the antenna to prevent radiation from traveling back down the coax.

I have heard a lot of good reports from people that use them. I understand that there are about three grades of the screwdriver antennas. The smaller ones have more loss than the larger ones. It is up to your budget as to whether you want to pay for that extra little bit of signal you get with the larger antennas.

I wish you the best on it.

Yes, if the spacing is correct and the pole is long enough, but it may
not be as efficient as a tuned element such as the reflector on a
Yagi.

What he wants is a cartoid pattern, That is a "D" shaped roughly
pattern that's all from and not so much back.

The easy way to do that is a good colinear and mount it near
the flat face of a tower (usually less than 1/4 wave away) . The net
effect is slightly increased gain away from the tower and a mild null
on the other side of the tower. Most of the time this is not desired
but, there are valid cases where you don't wish to waste power behind
you. The most common is coastal commercial broadcat radio and TV.

Charlie,

I just came across your posting. Thanks for sharing the photos, I really enjoyed them. I have the 6BTV out in the back pasture with just 16 radials and a criss-cross of left over chicken wire, and it has always worked great. Been thinking of "upgrading it" (as it is about 15 years old) to the DX Eng. tilt-over and ground plate, so especially liked your clear photos of how it went together.

"Hollow challenge"? I don't think you have the
facilities to do this....you're field seems to be
more along the lines of a bad used car saleman!

If someone can come up with a 3 element
yagi (we wanted to keep the size down), with
a 180 degree front lobe, and about 11 dB F/B
ratio, that has a better than 4.5 dBi in the
front lobe, i'd like to see it. Use EZNEC
or whatever simulator you have, and make
an H-plane plot... i'd like to see that.

Indeed. Basically like what i showed you:

http://www.drslick.org/Temp1/yagiplot.jpg

This "D" shape is suitable for when the broadcaster
wants some directivity, but will NOT be on the
extreme edge of the service area or town. It's
obviously not suitable if you are in the center
of town, unless you wish to focus more ERP
in the direction of some taller buildings,
for example.

If you are trying to get a feel for the pattern of the antennas in
"the real workd" you want to have your receiving antenna far enough
away to be making far field measurements. I don't have a definition
at hand, but it think it's somewhere between 5 and 20 wavelengths.

>desired direction) to essentially add to the desired angle of radiation,
>if only by some small amount.

Hi Rick,

This is true, but probably not for the reasons you may have
envisioned. Simply put, the metal acts as a shield to prevent loss to
ground. What is not lost is radiated in other directions. It aids in
those directions straight up, but it also aids in directions at every
other angle too - net result: better signal; how much: nothing
dramatic. This simple fact will probably get you more initial gain
than you will add doing anything further (short of building a tower
and putting up a beam).

>Is there an optimum angle of radiation for DX,
Yes - you may hit it poorly tho'.

>
>Though optimizing the location of the dipole for a particular angle of
>radiation seems good, there will also be a corresponding cancellation of
>signals at other (calculable) angles of radiation, right?
Odds are that given this vague description, that, yes, anything could
happen. Guessing your intent, well you are already in illusionland
with optimization - unless, of course, 1dB optimizations light up the
stars in your firmament.

>Is it all for naught anyway? Given the action of a wire reflector, will
>the sheet metal slab only look like a larger version and only in the
>general direction perpendicular to the center of the sheet metal axis?
Practical answer is no one will probably notice even if you could
shift everything around to suit your best guess. You have far more
dramatic opportunities (more than 1dB) with a vertical within sight of
the ocean.

>from my transmitter. So, I can't have an antenna that "eats" 90 percent
>of my transmitter ourput.

Hi Jimbo,

The simple numbers are radiation resistance and Ohmic resistance.
Which is larger? Answer that and you have a simple answer. What are
their proportions? Answer that and you have a more complex answer.
Think of a voltage divider (now a power divider).

Now ask yourself, what is the radiation resistance? What is the Ohmic
resistance? For quarterwave and smaller antennas, simple formulas
abound (or tables are available) for radiation resistance. For Ohmic
resistance, this is a function of materials and construction. In this
last regard, it only takes a loose wire, or screw and this resistance
climbs through the roof.

Let's put that into context. For a 12' vertical radiator operating on
160M, you have a 4/160th's wavelength radiator. Radiation resistance
is running on the order of 1/4th Ohm. If you manage to hold all Ohmic
resistance to that value, or lower (everywhere - in TOTAL) then you
verge on 50% efficiency, or better.

Your Mileage May Vary.

I have got a full size G5RV designed antenna. I intend making it into an 80 metre band doublet, and broad banding it using a 50 mm cage for the last 12 foot or so, than I intend, standing the 2 cages vertical in the supporting trees. So it will finish of as a huge U or 2 L shape. About 50 feet above ground. Has any one had a bash at this shape/ style of antenna? Also I have read about antenna modelling software, where can I get some, and will it cope with silly shaped antenna? Thanks

Been out of town - haven't had time to try anything yet. What size chokes would you recommend? I can stop by RatShack on the way home, or possibly detour up to HRO in Salem, NH...

Isn't the 706 supposed to use something like 300mW for tuning? Shouldn't this be under the threshold for RF interfering with the tuning control lead? I mean, if I can send Ethernet frames at a rate of 1Gb/s down a Cat 5 cable error free, you'd think I wouldn't have trouble with 300msec pulses...

You can lead a horse to water, still can't get it damp.

You'd have to look at the data sheet. All the commercial people
are aware of this and it's accepted practice.

What you missed is a 2 or 4bay dipole is a really nice antenna
that can offer gain and pattern control. The usual use is a 4 bay
vertically oriented with each of the 4 dipoles spaced 90 degrees
around the mast for 5.6db omnidirectional gain. Now, if you want a
directional pattern, such as cartioid then put all four on one side,
also expect slightly higher gain as well. The commercial version are
expensive but are known for their durability but, the good news is
they can be built using copper pipe and will give the same
perfomance. I might add, the gain numbers I gave are not theory,
they are real numbers from proven designs.

Ok, here are some links one how to build it..
http://www.repeater-builder.com/rbtip/exposeddipole.html
some good info here, the metal used is less desirable than
CU pipe. The general design is proven.

http://www.w4dex.com/kc4fwc/ant.htm
Info on making a phasing harness, needed for a 4bay but not
rocket science.

http://dipole.w4zt.com/ look at the plumbers dipole page.
This can be built as a 1/2/4/8 dipole array. The limit is 4
based mostly on size though I've seen one 8 dipole array
and it's long(nearly 45ft!) but very effective. I might add if the
mast pipe is made with 1" copper it can also serve as the supporing
mast. This is a prefered design and offers good all grounded
construction (lightining avoidance and static noise reduction).

The two dipole array with both on one side of the mast is the same
gain as the super jpole with two differences. the 4 bay will be longer
but offers a real gain increase and slightly better pattern control.
The gain increase for this type antenna is predictable, being 3DB
for each time you double the elements. The single being 0 DBd,
2bays 3Dbd, and 4bays 6Dbd . Thereal world the practical antennas
built as omnidirectional are really 0, 2.8 ,5.6dbd due to small but

measureable losses in the cables. If the elements are lined up on one side the gain is higher (sme claim 9db) with a cartiod pattern. It's all copper and no required insulators and can be built more robustly. The pattern is predictable, less is left to chance. This type of antenna also works well against the side of a metal building (less tuning difficulties) though you will get a more directional pattern from the building shielding the opposing direction. These designs will you get away from theory and use practical designs.

A repeater group I work with locally used the DBproducts 4bay and found it the best antenna they've put on the tower to date. It wasn't cheap and it was heavy. Experience at that site was anything less robust would barely stand a year before the SWR went to unacceptable. I've built the 4bay for UHF and it's a solid performer. The all copper design weathers very well, is very cheap to build and performs just as well as the commercial versions which are welded up from aluminum.

I'm sure your getting results from the Jpole but, I can be certain from using them myself that your results are part luck and can easily be attributed to the added height (the 70+inches can really help) and placement more than the presumed gain. If you compare a yagi or dipole to a J-pole the radiating element must be the same height. Since the J-pole is really an end fed dipole it has a 38 inch advantage. For a yagi the centerpoint is the boom.. In direct comparisons the yagi you built would have to be minimally 3ft higher to compete on fair ground.

J-poles in general do not like to be near (less than 1/2wave) metalic structures as it detunes them. Yagi behavour is also sensitive to metalic structures close to them. The Yo model is not complete enough for those cases.

A particle possessing a DC potential with respect to
the antenna. The mechanism of charge transfer from the
charged particle to the antenna is DC.

You likely pegged it.

Why anyone would use a yagi structure to get a pattern like that,
it's not the forte` of that kind of design. That badly a detuned yagi
would likely not perform as expected as well.

I kinda figured that out between the hacked up beam and the almightly
Jpole claims. Jpoles seem to be the holy grail of the pirates. Not
to put down the Jpole but it's suffered more snakeoil and used car
salesmanship than deserved.

Oh well, if someone wanted to do it right at least the recipie is
there even if Dr Slick doesn't fully appreciate it.

I have been using on of the small compact back lite cross needle DAIWA SWR/power meters, model CN-410M. It is only 3"x3"x4" and can be flush mounted.

It appears they are no longer manufactured.

Anyone care to suggest a suitable replacement for mobile HF operations? Compact size and flush mounting preferred.

Thanks,

Greg

Try using a shielded 4 conductor cable. All the stuff about ferrites is
good but if you can prevent pickup in the first place, that is better.
Also try ferrite beads on the ICOM interface control wires inside the
tuner.

It will not happen anyway. That is not a real problem. The real problem is most of the gold/Teflon PL259's I've seen are not very good connectors. One batch I had was giving me trouble soldering the braid. So I measured the inside diameter of the area where the 4 holes you solder the braid through. It was 0.050" bigger in diameter than the good amphonal connectors I normally use. It made it hard to solder trying to fill that big of a gap.

The Super J-pole was actually about 5 ft. lower than the
Yagi, so it evened out in the end.

But if you read it carefully, you will
note that i only am stating the conditions whereby the
final transistors will not be blown, which is
a 50 Ohm dummy load or a properly tuned antenna.

But I don't encourage anyone to break the law,
heaven forbid!

Try google, or better yet do a little work. I've already done a fair bit.

> 2 bays is big and heavy enough! 4 would be
>a bit overkill in this situation.

Not likely.

> I've tried using an SO-239 attached to the

>a bad idea...pot metal is very weak.

It's a good idea, use a good connector, most of the quality ones are nickel or siver plated brass. The ratchack ones are garbage. I prefer Type N connectors as they are easier to waterproof and good ones are quite solid.

> yeah, but UHF versus VHF is gonna be a huge
>difference weight and size wise!

Yep, 3:1. Use light metal. Though using 1/2 inch copper is not as heavy as it may seem as it's also structural. I have built them for VHF too.

Of course for 100mhz FM use they do grow a bit and may be too obvious for a stealth operation.

The rules are simple. Want more signal, put up more metal.

Allison

>
>Tam/WB2TT

Usually gold to tin is ok. What can be a problem is if the gold is
over copper rather than nickel for the edge card connectors. I had a
few computers that were "poisoned" with connectors that had gold over
either poor nickel or non-existent nickel plate and they were very
problematic with copper migration. They developed a "shake well
before using" problem requiring the system to have the cards pulled
and reinserted to break through the film that resulted. The gold
connectors tend to loose their gold shine and turn greensih to dull
gray if thats a problem. Never had that problem with PL259s/SO239s.

I have had some cheap silver/gold PL259s given to me that were
dimensionally sloppy, likely cheap manufacturing.

However, it is exactly these aspects that make human hearing terrible
for side-by-side comparisons like the one initially described by the OP.

There are plenty examples of double-blind tests that indicate that the
participating observer often makes the worst sort of qualitative judgements.

Human judgement is a useful tool, especially when trying to understand
the hard-to-quantify. However, I find it dubious that anyone has ears
good enough to hear the quality of an audio signal that is the result of
+- 1dB of RF gain presented to the front-end. (This is not to say I

think that the OP only used this method to get his/her results.
Clearly, the OP used some sort of methodology to obtain the +1dB gain
claim. I only suggest that we should be critical of qualitative
results that back up the results we want.)

Results to the contrary from a proper double-blind test backed up by
multiple datasets based on what we /can/ measure would convince me
otherwise.

A better qualitative test would be to simply live with the antenna for a
few weeks, and see what DX one could pull in. Again, totally
unscientific; but this is what average radiopersons (like me, I'm
afraid!) have been doing for decades now.

I look at this sort of thing as an example of the "right tool for the
right job."

Most of these are no longer on the web, but they were on 9-19-03 when I originally posted them here:

From http:www.metroactive.com/papers/metro/08.28.97/beat-9735.html:

I missed Creech but got to hear a tape of the band's performance two days later on a micropowered radio station broadcasting at 91.3FM out of Los Gatos known as Radio Free Lost Gatos. The guys in Creech guest DJed, heckled callers and played the whole of their set along with some of their favorite bands. According to RFLG owner/manager/DJ Dr. Slick, the station has been operating out of a house "buried in the Los Gatos hills" for three years. "I do it for fun," Slick says. "I don't do it because I'm an 'anarchist.' I don't go out and say, 'Kill the cops.' I'm positive with radio."

Slick was mum on the wattage but said that 91.3 reaches all of Los Gatos and parts of Campbell. Slick plays classic rock, jazz and "a little bit of Bach" when not turning the controls over to guest DJs like the members of Creech. The station can be heard Sundays and Wednesdays, 8pmï¿½3am. Meanwhile, the next Gaslighter Theater show stars Monkey, Blue Beat Stompers, Steadyups, Lucky Strike and Pigs in Space on Friday (Sept. 5). As always: all ages and five bucks.

From http://www.svcn.com/archives/lgwt/05.06.98/PirateCat.html

Monkey Man stepped into the world of microbroadcasting about a year ago, with his friend Michael Magic at Free-Radio San Jose, 93.7 FM, but had to leave the station after some of his on-air hi-jinks went too far. After that, he started working with Dr. Slick, whose station, Free-Radio Los Gatos, is on 91.3 FM on Sunday and Wednesday nights from 8 p.m. to 11 p.m.

"Then Dr. Slick said I should get my own station, so I went down to Fry's and got one of those little radio kits for, like, $30." Dr. Slick gave Monkey Man an old one-watt amplifier, and another friend, Austin Tatious of KKUD 104.1 in Willow Glen, donated a mixing board. Pirate Cat was on the air.

---------- end of Web quotes ---------------

At the time, I asked:

"It looks like we can look forward to a bigger signal from Radio Free Lost Gatos (or is it Free-Radio Los Gatos?). No more 'all of Los Gatos and parts of Campbell'! Or are you be building FM transmitters and amplifiers for sale?"

It looks like we now have the answer.

2217. Re: Extending Icom AH-4 tuner control cable

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-08 22:32:58 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cubemq$sq8$1@sparta.btinternet.com>
Source record: 82303

I have much used an AH-4 tuner in conjunction with an Icom IC-735
transceiver for 5 or 6 years or more. On all bands 160 to 10m.

The tuner has always been located at the base of various end-fed antennas.
The tuner control unit has always been bolted, as intended, to the side of
transceiver. The transceiver has been used in three different rooms, at
different times, in the house with varying lengths of control cable and coax
running through 1" holes in brick walls.

The control cable to the tuner has varied in length and distance from a few
feet to about 30 feet.

The system has always worked fine. No chokes, ferrites or anti-RFI measures
have ever been used. No RFI has been experienced. No faults have occurred
except that one dial lamp in the IC-735 has failed and I'm too old to fix
it.

The length of control cable has been varied simply by inserting a length of
unscreened, thin-wire, pvc-sheathed cable, 5/16" diameter, using soldered
joints and an open-to-the-air tag strip.

At present there is an excess length of control cable, of unknown length,
which is strewn around the floor, partly coiled up, at the back of a long
bench. But no TVI.

I ve had various problems with Gold connectors too. On the last batch the
insulators kept pulling out.There may be some good ones out there but I am
begining to think the gold /Silver is just window dressing for inferior
products.

>Anyone care to suggest a suitable replacement for mobile HF operations?

Hi Greg, I have never used an in-line SWR meter in my mobile rigs. I did not think it would be helpful.
For tuning a HF mobile antenna I use an antenna analyzer. An SWR bridge could be used, but it is not as useful to me because the analyzer gives lots more info.
When you are going down the interstate at 75 mph and talking on the radio, the SWR meter will tell you (if you happen to look at it) if something is wrong with the antenna. If you did not have an SWR meter, you would know something is wrong, cause the RX would go deaf, or the TX would fold back (have to look at the TX).
Sorry I did not recommend a mobile SWR meter. Just listed the reasons why you could get by without one.

Tom Donaly wrote:
"DC stands for Direct Current,. What is a static direct current, charged particle?"

My dictionary says d-c: An essentially constant-value current that flows in only one direction." Another definition says: "It may be continuous or discontinuous. It may be constant or varying."

Static means stationary or fixed. A static charge is the accumulated electrical charge on an object.

Terman writes on page 288 of his 1955 edition:
"An amplifier having a frequency range extending from a low value up to the order of a megacycle or higher is termed a video amplifier."

Black level is that level of the picture signal corresponding to the maximum limit of black peaks. White level is the carrier-signal level which corresponds to maximum TV picture brightness.

Alternating current cycles, regularly, increasing and decreasing periodically.

An alternating current is assumed to be sinusoidal unless otherwise specified, but it could, for example, be triangular, square, or it could have some other form. If the wave is symmetrical about the zero axis, any number of complete cycles will have zero as their average value. Most amplifiers and transmission systems are not directly coupled. They use capacitors or transformers between stages. These can`t pass direct current, so this reference is lost in transmission unless other steps are taken for its replacement.

The effective value of a sine wave thet does the same work as direct current does is 0.707 x the peak value of the sine wave. Average of the sine wave is different. It is the average of many equally spaced values taken along the course, from awro to zero through one complete HALF cycle of the wave. This works out to 0.636 x the peak value of the sine wave (0.9 x 0.707).

Best regards, Richard Harrison, KB5WZI

Richard,

It is clear that you are not discussing a general Fourier Transform.
Everything you state below, while correct, refers to Discrete Fourier
Series analysis and Discrete Fourier Transforms, including FFT.

More generally, integral Fourier Transforms are widely, rigorously, and
correctly used to analyze pulse phenomena that are definitely not periodic.

The original spark for this thread was an aperiodic pulse. You chose to
"mandate" all sorts of conditions that may be useful in a particular
case but are not required for theoretical correctness.

73,
Gene

Hi Gene,

The simple truth to the matter would be resolved in your offering the "general" Fourier Transform that could accomplish this feat of rendering the spectrum of an aperiodic pulse without having to tailor the waveform. I will lead the way instead.

I would note, ironically, that this data would be discrete (not continuous) and would necessarily drive peripheral processes to approach this "general" Fourier Transform. In other words, to accomplish this generality you would be required to describe the aperiodic function mathematically from discrete data. I've done tons of multivariate regressions, and there are any number of "solutions" that each would exhibit quite different Fourier results. Nearly every regression suffers from the same issues I've already discussed for Fourier analysis - aperiodicity. Frankly such an approach would be inferior to rather simple windowing and performing standard FFTs. This, of course, strips D.C. from the data set.

Windowing has been studied for its qualities since Blackman and Tukey's seminal work "The Measurement of Power Spectra" written in 1958. This is the mathematical work that predates FFTs. Every constraint and reservation that I have describe arises from the pages of this slim volume in terms of what you describe as "general" Fourier. As I've said, I have worked with both the Integral solutions to Fourier Analysis and discrete FFTs for some 20 years. The cautions

and constraints are absolutely identical. Nyquist teaches us this, Shannon further instructs us.

The authors offer three methods to perform Fourier analysis: Spaced, Mixed, and Continuous. They report:
"The choice among these types will depend on their particular advantages and disadvantages, and on the availability of equipment, both for recording and analysis. In almost every case, however, the detailed problems will be surprisingly similar."
pg. 55

The concepts of windowing are revealed by Blackman and Tukey; and their necessity described at great length - per my summarized cautions. The notion of "prewhitening" is discussed so that a finite data record can be transformed (no practical Fourier analysis consists of an infinite record). Aliasing is revealed as a problem as a consequence of sampling (I cannot imagine our correspondent made a continuous recording with a 2.5GHz baseband recorder). Windowing is described in "general" Fourier (and Laplace) math (no one here wants to deal with these abstractions). Impulse data (Dirac functions) litter the pages. Analysis goes miles beyond power spectra to include autocorrelation math- all done in integral calculus. Should we go into covariability? How about Coherence? This last would be useful to prove that the data is even real (and likely as not, it fails this transform).

The long and short of this obviates the hugely erroneous report of measuring DC at the terminals of an antenna. There is absolutely no Fourier Cavalry coming to the rescue of a poorly stated problem with equally problematic data.

Tom addressed Cecil Moore, W5DXP. I`ll risk a breach of protocol and respond though I was not addressed.

Put a charge on a speck of dust, snow flake, or rain drop. Propel it through space by any means. The moving charge is an electric current. What kind of current depends on its trajectory. A unidirectional atraight trip is without doubt a d-c flow.

If the chrge is propelled regularly back and forth, it possibly qualifies as a-c.

If the charge lands on a bare antenna wire, it likely will abruptly give some of its charge to the antenna wire. In this case, the singular event is a pulse and a static discharge.

Best regards, Richard Harrison, KB5WZI

But any radio broadcaster worth his or her
salt will be able to tell APPROXIMATELY how many
watts a signal is producing (or ERP), especially since
we don't have ionospheric skip in the broadcast
band, all line of sight.

> Human judgement is a useful tool, especially when trying to
understand
> the hard-to-quantify. However, I find it dubious that anyone has
ears
> good enough to hear the quality of an audio signal that is the result
of
> +- 1dB of RF gain presented to the front-end.

-1 dB at 100 watts is about 79 watts, so
yeah, most people with a good receiver aren't
going to hear the difference. But some
people very familiar with the signal might

notice the difference.

-2 dB at 100 watts is about 63 watts, which
most people should notice, especially on the
fringe of the service area.

-3 dB is 100 versus 50 watts, and no
shit there's an audible difference!

(This is not to say I
> think that the OP only used this method to get his/her results.
> Clearly, the OP used some sort of methodology to obtain the +1dB gain

+1 dB was what our theoretical
difference was, but it may have been more.

Sorry, but we don't have a huge VHF anechoic
chamber, and the proper signal strength meter
to do this properly!

>
> A better qualitative test would be to simply live with the antenna
for a
> few weeks, and see what DX one could pull in. Again, totally
> unscientific; but this is what average radiopersons (like me, I'm
> afraid!) have been doing for decades now.
>

Like i said, I would love to have a
big VHF anechoic chamber, and place each antenna
on a rotor, and measure every 2 degrees or so,
with the proper uV/meter equipment, but
we don't have the $$ for that. Most people
don't, i don't know anyone who does.

It may be unscientific, but in a certain
way NOT, because you can get field reports from
many people, who all have different receivers,
and different antennas on their cars, etc... so
the results are more of an averaged response.

Bottom line is, is the signal more
intelligible and listenable?

Slick

Radio Free Los Gatos doesn't exist anymore, but thanks
for bringing up good memories!

We serve the San Jose/Milpitas area now.

Just because i build transmitters, don't mean
i encourage people to use radiating loads with them!
Dummy loads are a wonderful thing, and you can learn
so much about RF circuit design and the phase-locked-loop!

Definitely! You try putting up a VHF
Super J-pole yourself! You are probably
more used to UHF, so 4 bays doesn't scare
you, but at the broadcast band, you will need
some serious help.

I would love to see what a 4 bay
would do though, but you need serious
bucks to do that, plus alot of manual
labor...

He doesn't explicitely say brass in
his website, and looking at the picture, it
looks like a cheapie SO-239 made of pot metal.

It's a bad idea overall. I would
mount it with 4-40 nuts and bolts on
an aluminum plate, and then attach
that to the antenna.

I've had to take an antenna
down before, just to replace the
broken SO-239 that i used in this
way. Bad idea. You have to make
your antenna very physically strong,
unless you like to spend a lot of time
on your rooftop.

1/2" copper gets heavy with 2 bays, trust me.

Especially for something like the Super J.

>
> The rules are simple. Want more signal, put up more metal.

Or want more ERP, or a lower angle
of radiation, put up more metal.

I would agree.

>>Can't swear to it, but I seem to recall a problem with gold/tin
>>interfacing.
>>Gold migration?

Where I've seen this, is when the tin frets, with flakes of tin oxide that build up under the gold, and literally push the fingers away. Tin-Tin allows a gas-tight contact that dosen't fret, but the tin-gold is bad news, in a finger-type connector. Motion, even micro-scale heating and cooling motion, makes it happen.

I just helped a client through one of these this winter, someone changed a part number and ordered tin connectors for one half of what was supposed to be a gold-gold pair.

A treatment of De-Oxit helps a lot, but the real solution of course, is not to use tin against gold in that situation..

I don't know if it would affect something like a PL-259 though.

Sorry I did not recommend a mobile SWR meter. Just listed the reasons why
you could get by without one. .....

I couldn't get by without one myself...Who wants to drag an analyser around just to change bands, etc..Besides, I don't own an analyser. I never thought they would be that helpful...:/ Or at least I've never needed one for anything I've ever done...
Also, if you are driving down the road, and the antenna leans back and changes the load my radio sees, the SWR meter will tell me at a glance what the match is. You can have a 2:1 SWR or higher, and still not have a "deaf" radio. But thats enough to cause a foldback...How much depends on the rig..
I can tweak the antenna, or matching device very quickly to make sure I get full power out. I couldn't see having to hook an analyser
up to do that, while on a trip...But my SWR meter is in the radio. This

one reason why I preferred a IC-730 over say a TS-130, back when those were current rigs...I'm so spoiled on having the meter in the rig, I don't
think I could go back to not having it...I hate having to drag around an extra box for that...Naturally, my current IC-706 has a meter also.. Icoms have had internal meters since waaaayyyy back...Sure makes things a lot easier...Applies to portable too...As far as the original poster, I don't have a clue, being I don't need one outboard...I'd use almost anything as long as it worked...Even a cheap rat shack model would be fine.
But....If he wants to live as I do, he needs a different radio...:-/
On hf, my meter stays on "SWR" all the time. I never look at the power out,
or ALC.
If I see that meter/bar start swinging over, I know instantly, Houston, we
have a problem. But to each his own , I guess....

Toasters? No, you mean bed-warmers!

So basically, i sell bed-warmers for
the furtherance of one's knowledge of
FM broadcast electronics.

For the future I plan on marketing an
excellent line of specially shaped dummy-loads
that can accept a coffee mug on the top,
for keeping your coffee warm all day!

Hi Dave,

Also take a look at the BBQ101520 by Degen Designs.

This is a true compact mini-quad antenna. Additionally, the quad comes full strung and is ready to mount in about 1-1/2 hours or less.

2245. Re: Icom AH-4 tuner and IC-706Mk2G radio

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-09 15:00:50 UTC
From: Jon KB1HTW <kb1htw!@!arrl.net>
Message-ID: <cud8je$9k1$1@newslocal.mitre.org>
Source record: 82181

Had time last night only to take the tuner down off the roof and put it inside my shack, just inside the window. Extended the long wire another 60+ feet using insulated 14AWG stranded speaker wire running across the roof from the original wire's anchor point on one edge, down to the window, so now it's 135'+. RF ground is now a 45` length of the same 14AWG wire running anong the deck and ground. Opened up the tuner and verified that I have supply sufficient voltage at the tuner (13.7Vdc). Placed sleeved ferrite cores on both the radio end and the tuner end of the control cable. Tried tuning at 40/20/17/6m - still not working.

It's a killer when I can only work on it 20 minutes at a time. Hopefully Saturday or Sunday I can try a bit more focused troubleshooting, assuming the coming Nor'easter isn't too bad. I thought I'd try making it drive a balanced dipole (if I can pick up some 450 ohm ladder line this week), 75' each leg. They won't be straight, more like a J with the tuner at the mid-point.

Diamond Antenna makes a couple of small cross needle meters about 3.5"
square, the sx-20c and sx-40c, depending on the frequency range you
need. They're listed in the AEA catalog, or you could go to theeir web
site, or call 'em..

I have done both the super J-pole and 4 bays of Dipole
at both UHF and VHF. I've also tested the result with far better
hardware than you have. Beside being a ham I'm also commercial
licensed and have an extensive radio lab.

> I would love to see what a 4 bay

Your kidding right? I figure using both 1" copper water pipe, 1/2"
copper pipe and the various fittings to be cheap. How cheap?
Likely if you spent 50$us you spent too much for your materials.

> He doesn't explicitely say brass in
>his website, and looking at the picture, it
>looks like a cheapie SO-239 made of pot metal.

Looks aren't everything. Also potmetal is not solderable
and his was. I'm normal so I have to test with a file to know
what material the connector is. I can never tell from picture.

> It's a bad idea overall. I would
>mount it with 4-40 nuts and bolts on
>an aluminum plate, and then attach
>that to the antenna.

You can but, you are making work thats not required
and you run into dissimilar metal electrolytic corrosion
and plain old rust. Water intrusion is the death of coax
most often. I've worked in marine environments
(salt is corrsive) so I have seen what works. Buy a
decent waterproof connector. I'd say Type N if your
really fussy.

> I've had to take an antenna
>down before, just to replace the

Mine have spend years on a real tower, roofs and other sometimes more
difficult places to reach. I don't like height so if I put it up
it's staying.

>> Yep, 3:1. Use light metal. Though using 1/2 inch copper is not as
>> heavy as it may seem as it's also structural. I have built them for
>> VHF too.
>
> 1/2" copper gets heavy with 2 bays, trust me.

Ah yes, you know all. Some day I"ll post a picture of the antenna
farm both UHF and VHF. Never minding the ones I've given away.
I know what type M and type L 1/2inch copper pipe weigh, do you?

Two bays would use approximately:

6 19" lengths of 1/2" copper (less than 5$)
4 1/2 inch pipe caps (usually less than 20 cents each)
1 10ft length (partial) of 3/4 copper water pipe for the mast (Runs
about 8$ last I paid for one)
2 1/2 inch tees (79 cents)
2 3/4" to 1/2" tees ($1.49 expensive ones).

This is under 12 pounds and is self supporting to that height.
Plenty light enough for this girl. You could use Aluminum tube
to build this and really cut the weight.

> Especially for something like the Super J.

Since the super-j doesnt offer the same performance your
claim is specious. As to structural, The super-J often fails
badly at the center insulator and the phasing loop as descrbed often
rarely makes the winter here in the east due to ice, wind and
snow. New England winters are harsh on antennas.

I also have a standard copper cactus Jpole for 6m/2m/70cm (it's only
14 ft tall) made with 1", 3/4" and 1/2 inch coppper. A really robust
antenna.

>> The rules are simple. Want more signal, put up more metal.
>>
> Or want more ERP, or a lower angle of radiation, put up more metal.

Same rules. If you understood antennas you'd know you do not get
increased ERP (or the reciprical, more signal) without concentrating
the RF field. Simply said, to do that requires more metal.

Allison

> +1 dB was what our theoretical
>difference was, but it may have been more.
>

First the average reciever will not see the differnce unless right at
the threshold of detection (MDS). The only place I've seen a 1db
difference that was detectable is in really weak signal systems.
In those systems the 1DB differnce cosses the threshold from just
noise to marginally detectable. Such as EME or my favortie mode
troposcatter.

The average FM broadcast system TX and RX runs at high power because
the average FM rx has limited sensitvity due to the required wide
bandwidth. Those recievers require a much larger signals to hit an
acceptable signal to noise and rarely can differentiate between
a 1db difference.

> Sorry, but we don't have a huge VHF anechoic
>chamber, and the proper signal strength meter
>to do this properly!

Measuring 1db difference does not require all of that. As to a
propper field strength meter, specify a brand. They are not rocket
science and are easy to build. If you really want to see something
attend a Central states VHF society antenna gain test. They usually
hit .1db or better accuracy and have tested Jpoles. The results of
past years are posted at their site.

http://www.csvhfs.org/CSVHFANT.HTML

I'll point you to the 2004 results and specifically to the 144mhz
section where a Jpole entered scored a -2.8db gain compared to
a reference dipole (0db)

These things are easily tested and easy to verify. If your trying
to resolve to bettern than .1DB that may be harder but,
3DB is easy and tends to jump at you.

Yeah, but you need a serious tower
to put 4 bays on, esp. at VHF, which we don't have
the money for.

He should explicitely state that it
should be made of brass.

Also, solder has VERY little
mechanical strength. Almost none.

It's a bad idea.

You're correct on this one:

http://www.ssina.com/galvanic/

So then use a brass plate, and
stainless-steel 4-40 bolts and nuts.

But don't rely on solder and the
corner of an SO-239 for strength.

Opps! I meant to say 1" copper. 1/2" copper
is not strong enough for a VHF super J-pole.

Aluminum is not solderable.

The Super J-pole at VHF is big, and
it's worse depending on how high you want
to get it.

We used a length of Delrin rod for the center
conductor, it's slightly flexible but ultra strong.
Don't use a wooden dowel coated w/epoxy, it will break.

The phasing loop was something like AWG#4
solid copper wire. Hasn't failed for 3 years,
but Ca. is a bit less harsh, indeed!

Slick

2254. Angle of Radiation

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-09 17:52:37 UTC
From: John <my-callsign@qsl.net>
Message-ID: <F5sOd.6142$xY1.4607@newsfe1-gui.ntli.net>
Source record: 82190

Can someone tell me please an easy way to calculate the optimum angle of radiation from a transmitting antenna over a given path on the HF bands (160m - 10m)?

OK, I guess its all to do with the height of the reflective layer in play and the distance of the QSO but I'd really appreciate some clues as to how to work this out.

Thanks

John

An older lampkin, and also a tuned RF sniffer
with gain (at RF) so I only need milliwatts.

Doesn't matter much as it can be performed with uncalibrated
instruments and a simple field reference by using a simple dipole
as a reference antenna first and do A:B comparisons. You don't need
absolute levels, only ratios for good accuracy.

> Yeah, but you need a serious tower
>to put 4 bays on, esp. at VHF, which we don't have
>the money for.

The first tower was built for repeater site using EMT stacked one on
another with sleeve joints (poor mans swage) to 30 ft. Then I put the
4 stack dipole on that (its height was also 22ft VHF). It was done
for a commercial site that was to be temporary and cheap. Worked well
for nearly a year before we planted a DB products commercial 4 bay and
a telephone pole at that site when they decided to make it permanent.
Its about 10$ per ten feet to build and guy that arrangement.

> Also, solder has VERY little
>mechanical strength. Almost none.
>
> It's a bad idea.

If the connector is holding weight then something else is wrong
as you would normally secure the cable to the supports. Strength
is not an issue then. Also most cut a small slot so the corner is
acutally in a grove, adds imensely to strength.

> So then use a brass plate, and
>stainless-steel 4-40 bolts and nuts.

Don't forget locking hardware as vibration and themal creep are
problems. You still get galvanic effects. Also drilling holes in the
structure to support the plate detracts from the structures strength.

>> This is under 12 pounds and is self supporting to that height.
>> Plenty light enough for this girl. You could use Aluminum tube

>> to build this and really cut the weight.
>>
>
> Opps! I meant to say 1" copper. 1/2" copper

But for the multibay dipole the 1/2 insections are only 19 iches and
very robust for that. The dipole portion could also be done with 1/4"
refrigeration tube as the structre is small.

> Aluminum is not solderable.

Again your wrong. It's solderable but, you do have to know how and
use a decent heat source. Though bolted connections would work.

> The Super J-pole at VHF is big, and
>it's worse depending on how high you want
>to get it.

Yes it is.

>> Since the super-j doesnt offer the same performance your

> We used a length of Delrin rod for the center
>conductor, it's slightly flexible but ultra strong.
>Don't use a wooden dowel coated w/epoxy, it will break.

Delrin works, not easily obtained and often not the right size
meaning a machine shop may be needed. Doesnt solve
the problem of the phasing loop sagging and failing.

> The phasing loop was something like AWG#4
>solid copper wire. Hasn't failed for 3 years,
>but Ca. is a bit less harsh, indeed!

CA is timid save maybe for wind and mountain weather. The use of #4
CU is very heavy and adds to the problems. The problem in that case
is #4 has a low strength to weight ratio. Most use hard drawn 1/4"
copper or brass tube which is far more satisfactory.

I've had 2 Comet base loaded 2 meter mobile antennas degrade after a year or so apparently due to condensation inside the so called sealed base coil. I've now drilled a small weep hole near the bottom in the second one and it seems to be drying out and working again.

There is no such thing as a sealed container outside. You need a small hole to let the water out. Water will always get in by condensation.

Nah, thats not the effective path.

Do the play lists get recorded and is RIAA paid? Seems they
are far nastier than the FCC.

Message-ID: <cuds62$4vq$1@titan.btinternet.com>
Source record: 82199

The elevation angle of a radio wave is not related to antenna construction.

It is calculated by trigonometry and is geometrically related to the distance between two points on the Earth's surface, the height of the ionospheric reflecting layers involved, and the number of hops.

If a radio wave leaves the Earth at one end of the path and returns to Earth at the other end, then the elevation angles of the path taken are the same at both ends. And the same in the other direction. (To forestall nitpickers let it be said things can vary around averages.)

The optimum angle at which to point a radio antenna, either for transmit or receive, is obviously the same as the elevation angle of the radio path.

BUT NO AMOUNT OF WAVING THE ANTENNA ABOUT WILL AFFECT THE ELEVATION ANGLE OF THE RADIO PATH.

For given points on the Earth's surface, height of reflecting layer, and number of hops, the angle of elevation of the radio path is fixed.

The angle at which the radiation from an antenna is a maximum is an entirely different matter.

Calculation of a path elevation angle on a curved Earth not very difficult but is a little too complicated to be written here.

Up to 1500 groundpath miles the Earth can be considered to be flat. Trig calculation is then schoolkids stuff.

Full formulae can be found in maths books under "Spherical Trigonometry" or in practical radio engineering books.

Calculations can be interesting but are invariably roughly approximate because layer height involves guesswork. And by the time you've finished a calculation the height has shifted. Or the number of hops has changed from 2 to 3. The only things which remain static are your own latitude and longitude.

To calculate propagation statistics of one and two hop radio paths, including elevation angles, download simple program TWOHOPS in a few seconds from website below and run immediately.

Try this out, it works!!!!
Turn $10 into $10,000 with PayPal..Easy & Quick
PLEASE TAKE A MOMENT TO READ THIS INFORMATION. THIS REALLY WORKS!!!
" I WAS SHOCKED WHEN I SAW HOW MUCH MONEY CAME FLOODING INTO MY PAYPAL ACCOUNT." -Mark 2004
Dear Friend,
This is a new program as you will see. It can be for the U.S. Canada, S.E Asia or the U.K. This is a fantastic opportunity, try it for yourself!! EVERYTHING DONE ONLINE! With just $10 or £5 and a Paypal PREMIER or BUSINESS account, you could make $$Thousands$$ in 2 SIMPLE STEPS!
GUARANTEED - you will have $10,000 in two weeks. Only $10, a Paypal PREMIER or BUSINESS account and 30 mins. are all that is needed to get this going. If you want to make a few thousand dollars real quick, then PLEASE take a moment to read and understand the MLM program I´m sharing with you.
NO IT´S NOT what you think. YOU DON´T have to send $10 to five or six people to buy a report, receipt or get on their mailing list. Nor will you need to invest more money later to get things going. THIS IS THE FASTEST, EASIEST PROGRAM EVER! You will be able to complete it in LESS THAN 30 MINUTES and you will NEVER
FORGET THE DAY YOU FIRST VIEWED THIS ONLINE.
If you´re already running a home business, you can easily do this one along with it. If not, this is the FASTEST and EASIEST way to earn serious money online that you´ve ever seen so far in the history of the Internet! This
program works no matter what country you are in, or what currency you use. It doesn´t matter how old or how young you are. And you certainly won´t need any special knowledge or talent. You won´t need to run a website, or make phone calls, or make photocopies, or send out letters through the mail, or pay for advertising, etc. The only things you will need are: * An email address
* A Premier or Business PayPal account with at least $10 deposited in it
* 30 minutes of your time
ONLY 2 SIMPLE AND EASY STEPS ! !
If you are doing other programs, by all means stay with them. The more the merrier, BUT PLEASE READ ON!! First of all, there are only TWO POSITIONS, not four, five or six like many other programs. This program is more
realistic and much, MUCH FASTER. Because it is so easy, the response rate for this program is VERY HIGH and VERY FAST, and you will receive your reward in FOURTEEN DAYS. That´s only TWO WEEKS! Not one or two months. Just in time for next month's BILLS.

TRUE STORY -- Grace Kelly tells how she ran this gifting summation four times last year. The first time, she received $6,000 in cash in two weeks and then $14,000 in cash the next three times.

THIS CAN AND WILL WORK FOR YOU! HERE ARE THE DETAILS:
Post this letter in 50 message boards, chat rooms, or newsgroup. You don´t need to post 200 like other programs or email 100 people just to get started. Even if you are already in a program like the send twenty dollars to six people. CONTINUE IT and stay with it, THOSE DO PAY OUT, but do yourself a favor, DO THIS ONE TODAY as well, RIGHT NOW!!! It is simple and takes a very small investment, only $10 and a Paypal PREMIER or BUSINESS account. IT WORKS AND IS DONE IN 2 SIMPLE AND EASY STEPS ! ! This program WILL PAY FASTER before the other programs you are working on even trickle in!! Follow the simple instructions and in two weeks, you should have $10,000 because most PEOPLE WILL RESPOND due to the LOW ONE TIME INVESTMENT, SPEED AND HIGH PROFIT POTENTIAL, PLUS, since its done all ONLINE, there is no time wasted mailing out letters and the such!!! We are not even figuring a 50% response! So let´s all keep it going and help each other in these tough times. We all owe money to bill collectors, and creditors. But, with this, if people take the time to help each other, the good fortune will follow. SO, Take the measly minutes this SIMPLE
and REWARDING program offers and give the gift that gives back TODAY!!!
HERE´S WHAT YOU NEED TO DO...
STEP 1 Ok, if you´re not already a PayPal user,
the very first thing you need to do is use the PayPal link below and SIGN UP. It takes just two minutes! Here´s the URL. Just click on the PayPal link below:
https://www.paypal.com/us/cgi-bin/webscr?cmd=_registration-run
Be sure to use this link so you can sign up for a free PREMIER or BUSINESS account. You´ll need to have a PREMIER or BUSINESS account (and not a PERSONAL account) otherwise you won´t be able to receive credit card payments from other people.
STEP 2
It is an undeniable law of the universe that we must first give in order to receive. So the first thing to do when you have your Premier/Business PayPal account is to IMMEDIATELY send a $10 payment from your PayPal account
to the person at POSITION #1, if... -- your
birthday is BETWEEN JAN 1 THRU JUNE 30, OR, if...
-- your birthday is BETWEEN JULY 1 THRU DEC 31, send the
gift to the person at POSITION # 2,
along with a note saying: "HERE IS A $10 GIFT FOR YOU." Be certain to add this note, as this is what KEEPS THIS PROGRAM LEGAL. Instructions on how to send a payment are under "SEND MONEY" at the Paypal Site.
It´s so Easy!!!
When you send your $10 payment to the first address in the list, do it with a great big smile on your face because "as you sow, so shall you reap!" When this program is continued, as it should be, EVERYONE PROFITS!!

DON´T BE AFRAID to send gifts to strangers. It will come back to you ten folds. A person can give you up to $10,000 per year and you don´t have to report it to the IRS!

Here are the current positions:
* POSITION#1 --- nxbrennan@hotmail.com
* POSITION#2 --- executioner_2k@yahoo.com

After you have transferred a $10 payment to the email address, something very eerie happens. It gives you an indescribable, overwhelming sense of certainty, belief and conviction in the system. You´ve just proved to yourself
that, because you have done it, there must be a great number of other people ready to do exactly the same. Thus you have now seen for yourself, first hand, that this business actually works!

REMOVE the email address you are replacing (the one you sent $10 to), and REPLACE it with your own email address.
REMEMBER: Use the same EMAIL ADDRESS that is used with YOUR Paypal account !!!
Paste your newly typed email address over the old one and
then post to 50 Message Boards, Chat Rooms, or Newsgroups. DON´T MULL OVER IT, JUST 30 MIN OF YOUR TIME, THAT´S IT THERE IS NO MORE TO DO!!
ACT FAST AND GET THE GIFT. HONESTLY AND INTEGRITY MAKE THIS PLAN WORK!!
DO TO OTHERS AS YOU WOULD HAVE THEM DO TO YOU. YOUR NAME COULD CYCLE FOR A LONG TIME ! ! THIS MAKES IT THE GIFT THAT KEEPS ON GIVING.
This is excellent seed money to start or expand a business, buy your dream home, car, and pay off what ever bills you may have.
Good luck and God Bless. Play fairly, Good fortune will follow.
WHY THIS PROGRAM WORKS:
!! HONESTY AND INTEGRITY !!
Straight to the point, the reason this program is SO SUCCESSFUL is because when you follow these instructions EXACTLY = GIVE A $10 GIFT and POST this in 50 different message boards, there are only TWO outcomes.
(1) A persons birthday will fall on the same half as yours, therefore, YOU GET THE $10...
OR,
(2) a persons birthday will fall on the other half of the timeline, therefore, YOU STAY IN YOUR POSITION and
get posted in 50 other MESSAGE BOARDS, etc...
BOTTOMLINE: Either you get the $10 or your name gets passed on for other people to give YOU $10 or pass YOUR name on to other people that will. It makes you think though, the more you POST YOUR OWN POSTS, the BETTER the results!!!
4 FACTORS THAT MAKE THIS PROGRAM SO SUCCESSFUL...
* EXTREMELY FAST RESPONSE
* EXTREMELY HIGH RESPONSE RATE
* UNLIMITED PROFIT POTENTIAL
* QUICK, SIMPLE AND CHEAP TO GET STARTED
So there it is. You now have the knowledge that will enable you to make

over $10,000 within the next two weeks. The only thing that can hold you back now is a lack of faith or a lack of self-belief. However, any doubts you may
currently have will disappear within a few days of putting this plan into practice. Trust me on this! You certainly won´t regret it.
SOME NOTES FROM PAYPAL WHICH YOU MAY FIND USEFUL:
PayPal lets you pay anyone with an email address and is the world´s Number 1 online payment service. PayPal is accepted on over 3 million eBay auctions as well as a countless number of online shops. You can also use PayPal to pay your friends - for example, it´s a convenient way to split the phone bill with your room-mate, send cash to your kids in college, or send cash to someone in another country. Better yet, you can also earn a referral bonus of up to $100 each time someone signs up for a PayPal account using your referral URL! When you send money through PayPal, you can fund your payments with your credit card or checking account. You won´t have to worry about your privacy, because PayPal keeps your accounting information safe and secure. Making a purchase
with PayPal is far more secure than mailing a check or giving your credit card number to a stranger. That´s why over 9 MILLION people from around the world use PayPal to move money. Signing up for a PayPal account is free, easy, and it takes only a couple of minutes.
Thank you, and good luck in your ventures.

2266. Quick and Easy Money

Try this out, it works!!!!
Turn $10 into $10,000 with PayPal..Easy & Quick
PLEASE TAKE A MOMENT TO READ THIS INFORMATION. THIS REALLY WORKS!!!
" I WAS SHOCKED WHEN I SAW HOW MUCH MONEY CAME FLOODING INTO MY PAYPAL ACCOUNT." -Mark 2004
Dear Friend,
This is a new program as you will see. It can be for the U.S. Canada, S.E Asia or the U.K. This is a fantastic opportunity, try it for yourself!! EVERYTHING DONE ONLINE! With just $10 or £5 and a Paypal PREMIER or BUSINESS account, you could make $$Thousands$$ in 2 SIMPLE STEPS!
GUARANTEED - you will have $10,000 in two weeks. Only $10, a Paypal PREMIER or BUSINESS account and 30 mins. are all that is needed to get this going. If you want to make a few thousand dollars real quick, then PLEASE take a moment to read and understand the MLM program I´m sharing with you.
NO IT´S NOT what you think. YOU DON´T have to send $10 to five or six people to buy a report, receipt or get on their mailing list. Nor will you need to invest more money later to get things going. THIS IS THE FASTEST, EASIEST PROGRAM EVER! You will be able to complete it in LESS THAN 30 MINUTES and you will NEVER
FORGET THE DAY YOU FIRST VIEWED THIS ONLINE.
If you´re already running a home business, you can easily do this one along with it. If not, this is the FASTEST and EASIEST way to earn serious money online that you´ve ever seen so far in the history of the Internet! This
program works no matter what country you are in, or what currency you use. It doesn´t matter how old or how young you are. And you certainly won´t need any special knowledge or talent. You won´t need to run a website, or make phone calls, or make photocopies, or send out letters through the mail, or pay for advertising, etc. The only things you will need are: * An email address
* A Premier or Business PayPal account with at least $10 deposited in it
* 30 minutes of your time
ONLY 2 SIMPLE AND EASY STEPS ! !
If you are doing other programs, by all means stay with them. The more the merrier, BUT PLEASE READ ON!! First of all, there are only TWO POSITIONS, not four, five or six like many other programs. This program is more
realistic and much, MUCH FASTER. Because it is so easy, the response rate for this program is VERY HIGH and VERY FAST, and you will receive your reward in FOURTEEN DAYS. That´s only TWO WEEKS! Not one or two months. Just in time for next month's BILLS.

The original poster, John, had already indicated the answer to his own question - but Reg was the only one who recognized that and had the correct follow up. Congrats, Reg.

I have a High Sierra Sequoia and have used it with great success. You need a good radial setup for optimal use, I made a set of eight 10FT long #12AWG stranded which I arranged in a spoke around the antenna.. I use this for mobile/portable setup; e-comm and field day. I have a mount on my deck rail and 144 sq ft of chicken wire under the deck for a ground plane; but the ground mounted antenna and radials work more efficiently.

I have a Carolina Windom strung up in the trees at home, black wire, fed with coax buried from the house to the tree line. HOA has never noticed I have an antenna up.

Thanks for all of the great replies! I think one of these antennas is going to work for my "stealth" antenna. I have read the various web sites that offer "screwdriver" antennas until my eyes are crossing. Everyone seems to be trashing eveyone else. Very hard to determine who is straight and who is bull-------. Can anyone offer some insight into stuff like coil diameter vs coil length vs "radiation efficiency" vs anything?

I know that I want full band coverage 10-160, and I only have 100 watts from my transmitter. So, I can't have an antenna that "eats" 90 percent of my transmitter ourput. So what should I look for in a "screwdriver" antenna that will give me the best performance with my specifications and limitations?

Thanks for any advice, jimbo

Wrong. Tap Plastics. In sizes that fit
3/4" or 1/2" or 1" copper perfectly.

Delrin is perfect for the Super J.

Don't use wood.

Our phasing loop doesn't sag and
hasn't failed yet.

> > The phasing loop was something like AWG#4

It may have been #6, but it was fine
for our purposes.

Slick

Try it someday.

> Ok, you can solder aluminum, but most

There are fluxes and solders for this at every local hardware.

> Delrin is perfect for the Super J.
>

Wood is poor.

> Our phasing loop doesn't sag and

Wouldnt last through the 30 inches of snow we got here.

> It may have been #6, but it was fine
>for our purposes.

Marginal.

Wanna try a real broadcast FM antenna, try a dual cycloid. Not to
hard to build but has both vertical and horizontal polarization. good
gain too.

Allison

2273. Angle of Radiation - Hawaii

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-10 03:49:58 UTC
From: Rick Frazier <rickf@rickfrazier.com>
Message-ID: <420ADA61.CF307A66@rickfrazier.com>
Source record: 82210

Hello:

I live in Hawaii, the land of metal roofing, and got to thinking on the way home tonight, that instead of complaining about it, I may be able to put the metal roof to some sort of advantage with regard to DX communications.

I'm thinking I can set the angle of radiation for a horizontal dipole, by hanging it the proper distance above (and or towards or away from the desired direction) to essentially add to the desired angle of radiation, if only by some small amount.

Think of the roof as an rf mirror about 60 feet long and 20 feet wide. Pitch is about 5 inches per foot, so it's a relatively low slope. A wire (source) located perpendicular to and centered on the roof/reflector would be a pretty high angle of radiation. Of course, the distance from the reflector to the dipole would want to be an optimum distance so it reinforces the signal instead of cancels it. One would think that this high angle of radiation should be able to be changed (shifted lower) by moving the dipole away from the desired direction of radiation. Of course, I would expect only a relatively small portion of the signal is actually affected this way, because the reflector is only a relatively small percentage of 180 degrees... Or, maybe not... A wire dipole, with a wire reflector behind it does increase gain in the forward direction, and the wire reflector is only an extremely small portion of the nearly 180 degree arc behind the driven element.

OK, now comes the fun part. There are (at least) three questions:

Is there an optimum angle of radiation for DX, (lower is better, to a point?) given that I'm 2300+ miles from the nearest land, and may be most interested in locations half way 'round the world and not just the nearest land, (which I can talk to just fine right now, thank you)?

Though optimizing the location of the dipole for a particular angle of radiation seems good, there will also be a corresponding cancellation of signals at other (calculable) angles of radiation, right?

Is it all for naught anyway? Given the action of a wire reflector, will the sheet metal slab only look like a larger version and only in the general direction perpendicular to the center of the sheet metal axis?

I've gone and done it now, got myself questioning more than I thought I knew... How 'bout you? Got any opinions?

Thanks
-_Rick

That would be a very good introduction to modern software like W6ELPROP. What it teaches you is that angles of arrival vary considerably, even for one given path, for reasons ranging from time of day to time in the 11/22-year sunspot cycle.

Remember that the F-layer is constantly changing height, especially if it's around around dawn and dusk at one of the reflection points. This means that at certain times the propagation has to 'flip' from say 3-hop-F to 4-hop-F, so the angle will flip too. And don't forget the E-layer, if that's there too.

W6ELPROP will actually tell you what propagation modes are the most likely at various times of day... and the reality is *much* more complicated than the simple pictures shown in older books.

The ARRL Antenna Book does rather assume that you can put up any antenna you can dream of; in which case, it will help you design the optimum system. Ideally, the antenna needs to be able to adapt to the needs of the moment.

But for most of us, it's much simpler than that. We can never achieve the low angles that are sometimes needed for some of the most important paths, so it simply comes down to doing the best we can. "Adaptability" comes down to possibly having a second-choice antenna... which at certain times may turn out to be better.

But even if we can't actually *do* anything about it, it's better at least to understand that arrival angles (or conversely, optimum launch angles) are actually very variable.

Looking at the ARRL Antenna book it seems that the angle of radiation is
pretty well fixed on the type of antenna.

Talking about "the" angle (as if there was only one) is misleading ourselves.

Every antenna has a *range* of angles over which it radiates (or receives) the best. The aim is to make that coincide with the *range* of angles over which signals are likely to arrive.

This is made very clear in the 18th edition of the Antenna Handbook onwards. It presents arrival angles as a statistical range of probabilities, over a spread of possible propagation conditions.

If you have only one antenna, then obviously you try to make its very best radiation angle coincide with the most *likely* angle of arrival. But it's a game of chance. Occasionally the angle may be very different from the most likely value, so you have to accept that you're going to be some dB down... or dead in the water. And that is where having a choice of different antennas really scores.

And ground losses are likely to be in the neighborhood of ten ohms
or about 2.5% efficiency.

Source record: 82126

I need some ideas on how to fix the problem with the G-450XL controller box.
I bought the controller box and the rotor from Ebay...it clearly stated that it had a problem with the controller so I bought it As Is thinking I could fix myself...here is the situation:

The left paddle (CCW), moves the needle counterclockwise but 1) not in accordance with the movement of the rotor. It goes very....very slow and when I stop pressing it it continues moving at the same pace (slooow) at this point the rotor has stop rotating. The Right paddle moves the needle along the pace of the rotor, just fine. Another problem is that the alert light remains on all the time.

Any ideas?

I operate a Part 15 station for my neighborhood (FM) and have acquired an AM transmitter. I've seen plans for vertical antennas but would rather make my own from the few parts I have. I have 8ft of aluminum tubing and would like to make a loading coil using 3 inch diameter PVC pipe. Given the frequency I operate on (1610khz), 8 ft of tubing, and a 3.5 inch coil form, how many turns of 22AWG insulated wire would I need to wrap? (Oh the tubing is in two pieces and I can slide the top piece up and down).

Is there a program I can download to find this out?

Hi Randall, I did this for a friend of mine a few years back.
Download the demo version of EZNEC and model an 8' vertical on 1.610
MHZ. You will find quite a bit of capacitive reactance. Your loading
coil should cancel the reactance. Determine the required inductance by
L=Xl/(2*pi*Fmhz). Xl is reactance you need to cancel.
The coil will be in the millihenries. Consult the ARRL Handbook for
a estimate on the # of turns on a 3.5" form for a given Inductance.

OK Gary, guess I'm a little dense on the subject but the EZNEC software is a bit complex for me. Can't seem to figure out the Reactance of my 8ft x 1/2inch aluminum antenna. I did find that the "SRC Dat" gave an impedance of 0.2714 - J 9981 ohms. How do I find the reactance?

I do have the 1988 version of the ARRL handbook and have found the formula for finding the inductance which in turn can be solved for "n", the number of turns.

Hi, Randall -

I have some information directly from the FCC concerning antennas for Part 15 (15.219 Operation in the band 510-1705 kHz) which I will share herewith. My intention is simply informative. I would encourage you to contact the FCC to clarify your own questions. As you can probably see, you must phrase your question as if you are a lawyer. My questions were sent to: labhelp@fcc.gov

I sent the following:

Part 15 regulations says:

[Code of Federal Regulations]
[Title 47, Volume 1]
[Revised as of October 1, 2002]
From the U.S. Government Printing Office via GPO Access
[CITE: 47CFR15.219]

[Page 732]

TITLE 47--TELECOMMUNICATION

CHAPTER I--FEDERAL COMMUNICATIONS COMMISSION

PART 15--RADIO FREQUENCY DEVICES--Table of Contents

Subpart C--Intentional Radiators

Sec. 15.219 Operation in the band 510-1705 kHz.

(a) The total input power to the final radio frequency stage (exclusive of filament or heater power) shall not exceed 100 milliwatts.
(b) The total length of the transmission line, antenna and ground lead (if used) shall not exceed 3 meters.

Concerning the 3 meters maximum length for antenna, transmission, and ground, would a capacitance hat at the top of a vertical radiator be included in the 3 meter limit?

For clarification: Suppose I put a 3 meter vertical monopole on top of an existing structure which has a metal roof. The transmitter would be located at the base of the monopole, so it would require no transmission line. Would I be allowed to install a 3 meter diameter (or more) top hat? The top hat would be shaped like a spoked wheel and would serve the purpose of increasing the current in the monopole through capacitive coupling to the metal roof ground.

Thanks for your assistance.

John Smith

The reply to this message from labhelp@fcc.gov was:

"Answer:

The intent of Section 15.219 is for a maximum 3 meter wire antenna.

The total length of the antenna plus ground lead plus connecting lead must not exceed 3 meters. The rule doesn't permit a 3 meter diameter "top hat" but should be applied to the combined length of each radial. If the combined length of each radial added to the length of the antenna vertical structure added to the length of the ground wire exceeds 3 meters, it would not be permitted."

I then sent the follow up questions:

"Thank you for answering my question concerning capacitive top hats.

I have two other questions about the 3 meter limit in Section 15.219:

Is a 3 meter diameter circular loop antenna allowed?

Is a square loop antenna of 3 meters per side allowed?

Regards,
John"

The reply from labhelp@fcc.gov was:

"I have two other questions about the 3 meter limit in Section 15.219:

Question:

Is a 3 meter diameter circular loop antenna allowed?

Answer:

No, the total length of the antenna must not exceed 3 meters.

Question:

Is a square loop antenna of 3 meters per side allowed?

Answer:

No, the total length of the antenna must not exceed 3 meters."

The point here is that you must be very specific. I suspect that, if you ask "Does a one foot diameter loading coil composed of ten turns constitute part of the antenna specified in the Part 15 regulations?", they will reply that the length of the wire in the coil is part of the antenna.

It would probably not be anything you should worry about unless someone complains, but, if you want to comply with the rules, you should ask them. Try to think like they do, not as if you want to beat the system. You already know they don't want your signal to go very far.

My post was designed to be helpful, not argumentative. I hope you will post your own findings here for everyone's benefit.

John

The reactance is the "J" part, and negative means capacitive. So at the source, the impedance is 0.2714 ohms of resistance in series with 9981 ohms of capacitive reactance. You'll need 9981 ohms of inductive reactance to cancel it out. That would mean an inductance of 9981/(2*pi*f), which would be 1.59 mH at 1 MHz for example.

If your inductor has a Q of 200 (which might be hard to do for that large an inductance), its loss resistance will be 9981/200 = 50 ohms. My guess is that your ground system will also have a resistance of about that, unless you put in quite a few fairly lengthy radials, giving you an overall feedpoint resistance of about 100 ohms. The efficiency would then be 0.2714/100 = 0.27%.

Brian, I did some quick F/B optimization runs runs with the NWplus
model you supplied me. I have included two different Nec-2 based
results. One with limited space in mind, the does require a bit more
space.

John, to get some more insight in this, I could suggest to take a look
at
http://elbert.its.bldrdoc.gov/pc_hf/hfwin32.html.

I must admit however that it will require some learning-effort.

If you found the angle of interest, you could then use any antenna
modelling package to determine the antenna height needed for the
frequency used. Or use HFTA for none-flat/sloping surfaces.

Source record: 82138

I'm putting up a long wire antenna for a SW receiver. The area I live in has severe restrictions, so I need to hide it, or at least have it not be obvious. For the end insulators I was looking for small, about 1" long skinny plastic or ceramic insulators. I know they used to be available, but I can't find them anywhere. Can anyone point to a source for them? All I can find are 3" insulators with a 1" diameter. These are much too obvious for me to use. Thanks.

Jer

2300. 50th pacc test 2005

PACC CONTEST

RULES 2005

DUTCH PACC CONTEST FOREIGN SECTION 2005

The Vereniging voor Experimenteel Radio Onderzoek in Nederland (VERON) has the honour of inviting amateurs all over the world to participate in the 50th Dutch PACC Contest.

Date and Period: Each second full weekend in February from 12.00 GMT on Saturday until 12.00 GMT on Sunday. So in 2005 the Dutch PACC Contest will be held on February 12 th and 13 th.

Bands and Modes: 160, 80, 40, 20, 15 and 10 meters, CW and SSB, no crossmode or crossband contacts allowed.

Please use frequencies according to the IARU Region 1 preferred contest segments:

CW: 1830 - 1850, 3500 - 3560 and 14000 - 14060 kHz

SSB: 3600 - 3650, 3700 - 3800 and 14125 - 14300 kHz

NOTE: SSB QSOs on 160 are not valid in the PACC contest!

Categories : Single operator, Multi operator, SWL and QRP (max 5 W max.output)

Exchange: RS(T) + QSO serial number, starting with 001. Dutch stations give RS(T) + Province abbreviation. These are GR, FR, DR, OV, GD, UT, NH, ZH, FL, ZL, NB and LB (total of 12).

Points: Each QSO with a PA, PB, PC, PF, PG, PE, PH, and PI station counts for 1 (one) point. Contacts must be confirmed with R, TU, OK or QSL. A station may be worked only once per band, irrespective of the mode.

Multipliers: 1 multiplier per Province per band, regardless of mode with a maximum of 6*12=72 or 5*12=60 if SSB only is used.

Final Score: The sum of all QSO points on all bands, multiplied by the sum of all multipliers on all bands.

SWL: Each different Dutch station heard per band counts for 1 (one) point. Multipliers as above. Logs must contain the codegroups transmitted by the Dutch station and the foreign station worked with.

Logs: As usual a score calculation is required. Please use a multiplier column and insert the multiplier in this column only if it is a new one.

Please sign log for observation of the contest rules. The closing date for contest entries is March 31st 2005.

Send your log to:

Hello All

I am thinking of some basic question about LO and I cant figure it out
I need your help to give me some explanation so I can further
investigate my text book.

Say there are 3 signals [frequency at wo-k, wo, wo+k]going into the
input of a LO. Then due to the nonlinearity of LO, we get
Intermodulation harmonics terms. If wo is the desired frequency while
the other two are interferers, my question is at which frequency Local
Oscillator will tune at?

For any theoritical and practical purposes, what is the method to find
the oscillator frequency and/or period?

Maybe this question sounds too general. Therefore, if you have any
further details to complement this question and doubts, kindly share
your views.
Thank you

rgds and thanks
Jason

Skinny insulators can be made from plastic coat hangers which come in
any number of different colors.

Instead of using special insulators just use some monofiliment fishing line
for the ends. You could even cut up a plastic ink pen if you need an
insulator.

Skinny insulators can be made from plastic coat hangers which come in
any number of different colors. ..

Dang...I had a post printed out saying the same thing, but
I noticed you beat me to it...:/ Good thing I checked...
Those work well, but the UV will kill them after maybe...
2-3-4 years...But for the price, replacements are not a
problem. The fishing line will work also...For normal use,
I've been whacking old broom sticks, or PVC into small bits
for insulators...I drill the holes at right angles, cuz most
seem to do that... MK

2306. Back Into Hobby: Some Basic Questions, Please

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-11 18:44:48 UTC
From: Robert11 <rgsrose@notme.com>
Message-ID: <odKdnR2mKMuGYJHfRVn-jA@comcast.com>
Source record: 82145

Hi,

Have finally gotten back into hobby, now that I am retired.

Have been reading the ARRL books, a bit, again, and realize I'm still quite confused over the antenna pattern diagrams they show for the various types.

a. What is plotted in these diagrams; the H field, the E field, or the resultant of the two ?

b. When they talk about field strength, what do they mean ? Again, the H field, or... ?

c. Have a receive-only antenna running around the 4 sides of my attic. Open at the end.
Should I tie the end to the beginning, making a horizontal loop up there, or not ?
Why ?

d. Do listening only, from 0 to 30 MHz, and from all compass points.

Would a straight run of wire along one side (thus foresaking the lengths provided by the other 3 sides)
gain me anything, or is the square loop configuration probably the best overall compromise
for pulling stuff in ?

e. Tried to find some but couldn't.
Any pix/diagrams on the web showing the lobe patterns as a function of frequency for:

a single random-length wire
a 4 sided loop, open at the end, like I now am using
a 4 sided loop, closed at the end

Thanks,
Bob

from the RadioDan site:

Henry will no longer make any tube type amplifiers or any HF
amplifiers!
Henry lost their main lease, effective 01-31-05
warranties will be honored, service & some parts will be available
Henry will continue to make vhf/uhf solid state amplifiers, order thru
radiodan
if you have any questions about the above info,
e-mail Ted henry at henryradio@earthlink.net

Hi Bob

Might be worth downloading and playing with 4NEC2 from
http://www.si-list.org/swindex2.html. This will allow you to model
antennas and check radiation patterns (incl E vs H) with and without
ground and other objects influence. Its GPL.

Also have a look at http://www.cebik.com for a stack of info on modelled
antennnas in the amateur service.

Cheers Bob VK2YQA

When all else fails, start at the beginning.

Found the problem. Cold solder joint on the PL-259 failed in the feedline - obviously due to temperature swings, since I solder perfect connections every time. Yeah, and the pope's Protestant...

Fixed it and now it works - almost. Twice now, a few minutes after it tuned, my radio by itself would key the transmit - both times while I was not even near it! I had to shut down power to kill it! Oh well, one more problem to troubleshoot!

Hi Jason,

This is a shaky start, the Local Oscillator has no input. I will
presume you are speaking of the Mixer.

> Then due to the nonlinearity of LO,

This pretty much confirms you mean Mixer (or converter).

>we get Intermodulation harmonics terms.

In abundance.

>If wo is the desired frequency while
>the other two are interferers, my question is at which frequency Local
>Oscillator will tune at?

All depends on the receiver's Intermediate Frequency. The LO is
always tuned to the desired frequency ï¿½IF. If you are tuning to
10MHz, then the LO is tuned to either 10 + IF or 10 - IF. There are
also Synchronous Detection receivers where you tune the LO to exactly
the desired frequency. There are other receivers that demodulate the
signal using other LO systems (your question is much to vague).

>For any theoritical and practical purposes, what is the method to find
>the oscillator frequency and/or period?

Use a frequency counter (but I presume that your question is not being
literal - which means you are being too vague again). My discussion
above your paragraph's question should have answered that already.

>Maybe this question sounds too general. Therefore, if you have any
>further details to complement this question and doubts, kindly share
>your views.

Try asking your question from the perspective of intended use rather
than framed with the presumed terms of an answer to an unstated
problem.

That should be expressed in the units consistent with H or E. If no
units are expressed, then it is usually a comparison with dB, dBi, or
dBd.

> a 4 sided loop, open at the end, like I now am using
> a 4 sided loop, closed at the end

Hi Bob,

The same geometry at all the different frequencies you propose do not
yield the same lobe patterns. That is your first lesson.

You express the desire to receive from all 360ï¿½ which will certainly
happen for many of the designs you describe above, but only through
happenstance and being in the attic (which means close to ground, as
in earth, not wood/stone/mortar).

What you want to concentrate on is keeping noise out of your antenna
(this will probably be answered in the course of the thread).

The long and short of it is without spectacular care, those lobes are
rarely observed unless you have your antenna in the air, and more than
a quarter wavelength above ground - difficult to do with your
> from 0 to 30 MHz,
...Quarterwave of 0MHz is pretty high up.

A simple dipole is handy, so is a loop, and so is an open loop, as is
a vertical, or phased elements - but only with respect to their size
at any particular frequency.

Your basic question is far more complex to answer than any complex
question which often resolves to a simple yes/no.

2313. Small loops for reception

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-11 21:40:00 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <qE9Pd.9498$Lu7.6995@fe09.lga>
Source record: 82152

For the first time in many years I have been listening a lot on the low bands (160/80/40). It seems there is much more background noise than when I was in my teens, but that may be my selective memory at work. I am in the far suburbs trying to use a half-sloper and an inverted V -- both with the peak at about 53 feet. I think most of the noise is "natural" (except for a 15Khz harmonic every now and then.)

I started reading about small loops for receiving on 160 and 80. In particular I have been reading about:

(1) the 4-turn loop on 4-foot cross arms (W1FB),
(2) the 4-turn coax loop (in a 9-inch diameter) (W1FB),
(3) an 18-inch ferrite rod unit described by G2BZQ

All of these were described as better receiving antennas "in the house" than the authors' more conventional outside antennas. W1FB thought the 9-inch loop was better than the 4-foot unshielded loop and apparently did not think much of ferrite-stick antennas.

What is the experience of those on this newsgroup? Are these antennas really better (in the house, and even in the basement) than conventional outdoor antennas? Are they significantly better when used outside and perhaps elevated a bit? I realize they are inconvenient because they must be tuned even for small frequency changes. It seems they are very directional for nulls but fairly broad for other responses. Is the same loop good for 160 and 80 (and maybe even 40)?

If you use insulated wire, you could even use push pins for supports and
run it along a fence.

2318. top vs bottom fed tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-12 00:32:25 UTC
From: ml <m@di.net>
Message-ID: <m-0B1A6A.19321911022005@news.verizon.net>
Source record: 82157

I was thinking about putting up a hopfully soon , to be built horizontal
center fed dipole

my plan now seems to favor a tuner like a sgc231

I sorta have 2 choices but want to know a few pro /con's

option 1 is putting the tuner ontop of the mast and feeding the dipole
pretty straight foward

option 2 would be to pu the tuner near the bottom of the mast (5ft)
and running some wire up to the top of the mast w/a glass insulator

questions

would it be ineficient to do option 2?? how bad would it be??

what type of run should it be, 450 ohm ladder line or just 2 wires run
spaced apart

does doing option 2 sorta defeat the point of using a far end tuner?

if that support mast in option 2 is metal, is that 'bad' how far must
my verticle wire be run away from the mast or must i use plastic/pvc??

I understand that the topside tuner would allow more power out over my
coax run, but this isn't my main concern as if i lost a bit of power i
just wouldn't mind or can compensate --i am more concerned about all
the other factors (tvi, resnonance, efficiency)

thanks

I found this same situation when I went to get on low band after 40 years
away from it.

I found that what sounded like natural background noise was not natural.

With a suggestion from a ham in Wisconsin, I found several insulators on
power poles near my home arcing. You can find these poles with a simple
battery powered am radio. Go back at night after you find a noisy one and
use binoculars to see the actual arcing. Now you can call the power company
and point out the bad insulator. This worked for me.

I have a 60 foot random wire antenna and it is very quiet now. Putting up a
loop will not fix the noisy insulators.
BTW these insualtors arc more in damp weather than when it is dry.

I'd like to caution you against using plastic that's not intended for outdoor use. Most types will deteriorate rapidly from the UV in sunlight, and turn brittle and very weak in a short time. Even here in western Oregon, most plastics become useless in a year or two, and in a place like Denver (5000 feet high and lots of sun) you only get a few months at most.

A better idea, in my opinion, would be to use fishing line as others suggested, or make your own from a piece of ABS pipe or something similar.

Hi OM,

Either will probably be indistinguishable from the other. If the
tuner is lower, then keep the twin line, or its facsimile away from
the metal support by three or so times the separation distance of the
two feed lines.

Don't forget to put chokes on the Transmission line to the tuner, and
on the control lines to the tuner - at the tuner inputs for each.

>
> a. What is plotted in these diagrams; the H field, the E field, or the
> resultant of the two ?

Either one. Once you get more than a fraction of a wavelength from an antenna, the E and H fields are in a fixed ratio (E/H = 377 ohms). So plots of the two are identical, except for the 377 ohm scale factor. The pattern is more often expressed in dB relative to some reference (most often to an isotropic source, expressed as dBi). This numerical value is then the E field, H field, or power density far from the antenna relative to the reference. The pattern shape and dBi value of all three are the same.

> b. When they talk about field strength, what do they mean ? Again, the H
> field, or... ?

Field strength technically means either the E field (in volts/meter) or H field (in amps/meter) but, as I said above, once you know one you can easily calculate the other unless you're very close to the antenna. Pattern plots are nearly always for the far field, where E and H have a fixed ratio and the pattern shape is the same regardless of distance. In the near field (which isn't of any interest for your application), the pattern is different for each distance, and the ratio of E to H isn't fixed. Therefore, near field data are usually given in tabular form.

>

> Why ?

Tying the end might change the pattern enough to make a difference in your ability to receive, depending on the directions of the signals you want to hear and of incoming noise. There's no single answer for everyone. You'll simply have to grit your teeth and experiment.

> a 4 sided loop, closed at the end

There are a number of free antenna modeling programs that will help you answer your questions. Just keep in mind that for HF receiving, gain in the desired direction is of no consequence by itself. The only thing that will help you receive better is to have a pattern that has more gain in the direction(s) of the desired signals than in the direction(s) which noise comes from. If the signal and noise come from the same direction, there's nothing you can do to improve your ability to hear signals. In that case, more gain will make both the signal and the noise louder in the same proportion. You can get the same effect a whole lot easier by turning up the volume control.

Hi Jason,

The Gilbert Cell was one of the first linear ICs and useful for
balanced Mod/Demod. What comes with it is strictly your choice
(regarding the question of IF or Synchronous Detection).

It would be simpler if you simply said what you need.

Monofilament fishing line breaks down very fast in the sun, you might
get a year out of it at best. If youï¿½re going to attach a Dacron, Nylon,
etc line to extend your wire, why do you need an insulator anyway?
Mike

How about using a wood dowel? Cut a suitable length, drill holes and
apply a few coats of varnish. Might work fine, though not as creative
as the poster who suggested buttons.

Roy et al.,

The polystyrene that plastic coat hangers are normally made from has a moderately good ultraviolet resistance - much better than nylon monofilament line.

But for a cheap, extremely effective, insulator which has excellent ultraviolet resistance, cut the top off a PET soft-drink bottle (where the screw threads are found). The dielectric properties are excellent and few plastics fare better to ultraviolet and acid rain exposure than does polyethylene terephthalate.

I have had a number of insulators up for years that were made from fiberglass loaded PET tensile test bars. The only problem was dulling of drill bits from the glass. A carbide tipped drill solved that problem.

Mine is closest to this one...Mine is a 44 inch per side diamond, using
5 turns.

> (2) the 4-turn coax loop (in a 9-inch diameter) (W1FB),

I have to wonder how he is tuning 4 turns on a 9 inch form?

Seems it would tune quite high in freq...

I have a 16 inch circular loop, but it takes about 12 turns to tune
MW..

> (3) an 18-inch ferrite rod unit described by G2BZQ

conventional

> outdoor antennas?

Depends on the use, and also depends on the source of the noise.
If the noise source is local, they can work very well to null that
noise. If the noise is just general atmospheric noise, the results
won't
be as good. Yes, the nulls are very sharp.

Are they significantly better when used outside and
> perhaps elevated a bit?

I've heard of people elevating, but myself, I'm not really convinced
it makes any difference. I keep mine on the floor, here in the shack
on stands, so I can rotate them. They work fine , even on the ground.

I realize they are inconvenient because they must
> be tuned even for small frequency changes. It seems they are very
> directional for nulls but fairly broad for other responses. Is the
same loop
> good for 160 and 80 (and maybe even 40)?

Ok for 160, but not really sure about the other bands. I use mine more
for MW use than anything...But mine does work 160m. The *best* time
for
a loop is actually in the daytime for MW ground wave use. They work
great
for that. They do help at night a bit as far as nulling some noise, or
unwanted stations, but the nulls on a skywave signal as not near as
deep
as for ground wave. To have a better idea if it's worth a try, will
probably depend on the source of your noise. If it's a local source,
could be worth a try. You can null that source down to nearly nothing..
But if you have multiple sources of noise, the results won't be as
good.
A loop won't be in the leaque of say a beverage or whatever, for say
160m dx...

Source record: 82077

I do NOT have experience of this, but using one's
background training as an aspiring engineer, I would
use the output of a calibrated signal generator as the input
signal, together with an accurate - and variable - attenuator.

Connect an RF Voltmeter to the output of the mixer.

Now you can plot input power against output power, assuming
that it is within your capabilities to assess the output impedance of the
mixer.

This should give you sufficient points to plot the response curve up
to the 1dB compression point.

However, there is a problem here, and that is, at the point at which
the straight line starts to curve off, you are not just measuring the
output power of the desired output, but also are including that of the
newly-arrived distortion products.

However, as I said, I don't have the answer for you (We are, after all,
amateurs and not professionals), but perhaps I have given you food for
thought?

I don't know exactly what you want to do, but I have used the Motorola MC1330 Synchronous Video detector as a CW-SSB/AM synchronous detector at a 9 MHz IF. The MC1330 uses Gilbert Cells. For AM you need an LC tuned circuit at the IF frequency; For CW-SSB you feed a BFO signal (square wave works fine) into the MC1330 at the same point. The DC level at the MC1330 output depends on the signal amplitude; so, that can be used to derive an AGC voltage. Tuning an AM signal is uncanny, in that a signal will sort of pop in.

You don't say how thick the wall is, but your best bet would probably
be a feedthrough adaptor with females at each end, combined with a
right angle connector. You could call the Wireman, RF Davis,
RadioWorks -- they all have web sites & phone numbers.

The feedthroughs come in lengths up to 12".

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed
God to save you. Welcome to the family of God.

If you decide to wait till later you may die before you get
another chance to be saved because none of us knows
exactly when we will die.

Have a great day!

2349. Re: Small loops for reception

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-13 01:47:44 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cumbk0$6uh$1@hercules.btinternet.com>
Source record: 82088

Very approximately -

To compare one loop with another, at a given frequency, the receiving sensitivity of small loops is very simply proportional to the area enclosed and tends to decrease as the number of turns.

Best to use very thick wire with a single turn loop (as with magloops) and a tuning capacitor to suit. Multi-turn loops are used ONLY because of availability of paractical sizes of tuning capacitors.

With a multi-turn ferrite rod antenna of given dimensions, sensitivity increases roughy proportional to the permeability of the core material but decreases according to loss in the core. Permeabilty increases the effective area enclosed. So use an HF core material - not one intended for VLF power transformers.

Ferrite rod receiving antennas appear to do very well ONLY because medium and long-wave broadcast transmitters are generally high power. They are high power because of the poor sensitivity of very small (in comparison with a wavelength) receiving antennas.

==========

Not having an Eastern religion I have no recollection of a past life. But the nearest I ever got to being a teacher in my present life was to teach myself after the age of 14. It all happened purely by chance.

Although in the last few years of my career I did present, by invitation, some one-day lectures to international audiences on the subject of how to locate faults on oceanic submarine cables. And even in those far-off days, when the repair ship captain chose to go 1/4-speed ahead and grapple for the cable, depended on what he had had for breakfast. I understand cables now contain optical-fibers but still contain a few copper wires for fault location purposes.

But submarine telephone cables were a small part of my career. However they did introduce me to transmission lines and communications in general. My first connection with radio began, indirectly, a few years earlier, during WW2, when I was a mechanical engineering apprentice in the tool-room and machine shop of a well-known electric-motor manufacturer. British-Thompson-Houston.

At the age of 16, while high explosives and incendiary bombs were falling on the industrial City of Birmingam*, I set-up and operated precision lathes and millers and broaches and shapers to manufacture what appeared to me to be very small electric motors. (As distinct from anything up to 1000 horse-power motors and generators which was normal production.)

Having joined the RAF in 1943 as a radar technician, in 1944, by chance, I came across these small electric motors once again. Actually, the articles I had helped to manufacture were top-secret selsyns to be used to synchronise airborne Radar plan-position indicating screens with their respective airborne, rotating parabolic antennas.

The radar equipment was installed in Lancaster bombers, the most efficient of the RAF's killing machines. The fire storms on German cities, almost as good as the gas chambers, were more efficient than the Hiroshima and Nagasaki weapons of mass-destruction. It just took a few hours longer.

The results of the latter weapons, in 1945, I witnessed and spoke to the few survivors while wearing my blue RAF uniform. There were no signs of animosity. The Japanese, an ancient educated and civilised people, were as polite to me as a sort of tourist, thousands of miles from my home in Birmingham (which they immediately recognised from a map sketched on the back of a cigarette packet) as they were to each other.

My programs and Mathematics. There's very little advanced mathematics in my programs. My arithmetic is entirely self-taught. But there's no two ways about it - maths is either all right or all wrong. And either way it can eventually be proved. That's the beauty of it.

University professors write books on it, plagiarise each other, and make a living under false pretences - but they add nothing except something illogical and misunderstood (usually a language problem) to haggle about in newsgroups. Same applies to radio. KISS.

The key to my programs is a logical understanding of distributed electrical circuits. It's just elementary electrical engineering. If YOU can understand them then you are well away. If you can't understand them then its because I have been deficient in my introductory notes.

Your comment on the 'excellence' of my programs is appreciated. But bear in mind, regarding quality, I have never claimed them to be numerically more accurate than needed for the purpose intended - whatever that may be.

==========

*On the same night as the infamous air raid on Coventry, a greater weight of bombs fell on the City of Birmingham and the industrial Black Country. Three days later fires were still burning in the adjacent town of West Bromwich. (These days West Bromwich is better noted for its football team.)

But Coventry, the City of Three Spires, three cathedrals, and Lady Godiva, was the greatest concentration of war factories in the UK. Tanks, guns, aircraft engines, fire pumps, motor vehicles, communications equipment were all being made in the city, all intermingled with inflammable medieval buildings to be ravaged by fire in the raid. Most of the human casualties were due to a single bomb - a direct hit on an air-raid shelter.

Incidentally, the 3000 MHz, 50 KW, Cavity Magnetron had just been invented by Randall and Boot in the Birmingham University laboratories which were themselves surrounded by large factories, under air attack, such as the well known Austin motor vehicle and the Aerial motorcycle works.

The magnetron was used to guide Lancaster bomber crews to their unfortunate targets where 10's of thousands of the inhabitants were burned alive, their husbands and brothers dying on the Eastern Front against Russian rockets and T54 tanks.

The magnetron was also used in the 5-year long Battle of the North Atlantic.

On the average a 10,000-ton food and munitions ship was sunk every day. More than 100,000 merchant seamen, civilians, without military pensions for their families, lost their lives in Davy Jones locker.

Towards the end of the war German submarine crews were on suicide missions. U-boat commanders, once detected by radar, had little option but to stay on the surface, uncover the guns, and fight it out. To submerge they were dead by depth charges. Their precise locations being located and remembered by airborne radar.

These days we have other forms of suicide. There are people who are living such enforced miserable lives and in such oppressed conditions they prefer to sacrifice their own lives in the hope of improving the future lives of their families and their decendents.

Citizens of the United States, and others, ask yourselves WHY?

Tonight I'm on a Bordeaux Claret. Vive L'entente Cordiale.

I know what a vacume tube is

and a capacitor

but never really heard of a vacume cap

what is it??

I've seen it in a tuner unit i was considering

thanks

A VACUUM capacitor is exactly what the name implies, the VACUUM
is the dialectric instead of paper or air.
It has bellows that is air tight, or should I say vacuum tight.

The other responder described an "adjustable" vacuum capacitor. The
more general vacuum capacitor has no bellows. The plates of a vacuum
capacitor are concentric or coaxial conducting tubes, which is not
that important. The important things are that they are sealed in
relatively heavy glass envelopes with electrodes at each end and are
capable of handling high RF currents at high DC potentials with
extremely low leakage.

Can a doorknob cap rated at 20 KVDC be used to
resonate a small loop?

Hmmm, I am pretty certain when they had it horizontally polarized and
end fed against another horse mounted knight, that they did indeed
appreciate that their armor served to counterpoise the inertia of
making a contact.

It does not appear to explicitly state in the app. note, but output IP3 is
calculated by taking the ratio, of the
desired output tone (all in dB) with the largest output 3rd order product,
dividing by 2, and adding to the desired tone. If the input
IP3 is required simply subtract the mixer gain from the output IP3. Take
not of the signs. If the mixer gain is < 0 then the input IP3> output IP3.

Yes, but the ceramic is only 1/2"-3/4" in diameter, and thus power limited. I've seen at least one used that way which
ended up in two pieces with lots of plastic shrapnel produced.

Sure, but I think you'd end up with a pretty poor antenna.

I don't know for sure, but guess that doorknobs are typically made from Z5U or similar ceramic. If so, the capacitance is a strong function of both temperature and voltage. Therefore, the loop tuning will change with both those factors. I'd also guess that the Q wouldn't be too hot, so you'd also incur a lot more loss than you would if you used an air dielectric part.

It's not just the voltage but the RF current too. If this is a compact loop,
the RF current can be high and just because a capacitor can withstand a high
voltage doesn't mean it an also pass a high RF current. The spec's I've seen
call out the max voltage and a max RF current for transmitting capacitors.

Reg, G4FGQ wrote:
"The fire storms on German cities, almost as good as gas chambers, were more efficient than Hiroshima and Nagasaki weapons of mass-destruction."

Just to quibble a bit, the atomic bomb was efficient for an explosive of its weight, equal to megatons of conventional explosives. My ship carried some of the first occupation forces into the Nagasaki area which I got to see. Our ship`s company armed ourselves and marched through town to see if it were safe to disgorge our soldiers there. Our captain outranked the army commander. The Japs were meek. They had suffered real stun and awe. Near ground zero about all that was left were fire-proof safes.

News here this week included a story on a German memorial celebration of the 60th anniversary of the destruction of Dresden by a single American/British airaid which produced one of those firestorms with massive conventional explosives and incendiary devices. The Germans don`t want to forget it.

The raid was of course OK as it was retribution for such destruction of English and other European cities.

Best regards, Richard Harrison, KB5WZI

2372. 2m Antenna for Pickup

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-14 02:57:52 UTC
From: Slip'er <cjhixon1@cox.net>
Message-ID: <esUPd.31024$xt.27785@fed1read07>
Source record: 82110

Elmer,
I'd like to install a 2m antenna in one of the stake pockets on my 02 F-150. For now I am just using a HT in the cab. Eventually, I'd like to put a mobile radio in there but the HT will have to do for now. Are some whips better than others? I just want a vertical whip for now (I need to keep the wife happy. The best would be a BNC connector that I could hide the antenna when she is using the truck...but I doubt that would hold up under 100mph highway driving). What do I need to consider when mounting the antenna? And what is the best coax to use? Tips on sealing the connectors? I am using a Vertex Standard VXA-700. Is there a whip that works well on TX for aviation and 2m bands? My emphasis for now is 2m though. I've read enough to make something work...I'd just like sage advise of folks who have been there and done that...

Feeling like a CBer right now, can't wait to start homebrewing my base station...but I need to get ready for a trip in 1 week!

Thanks,
Carl
[so new my call isn't in the database yet...I think it's lost!!!]

2373. Announcing a New Release

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-14 05:41:00 UTC
From: W9DMK <nobody@crosslink.net>
Message-ID: <421039bf.55842907@news.crosslink.net>
Source record: 82112

Announcing a New Release ---- SmartSmith version 1.7.2
SmartSmith is a free Smith Chart Plotting program.

Since the last publicized release (ver 1.6.2), there have been many
improvements, as follows:

Main Window -
The main window has been re-organized to separate the transmission
line data and to move the current admittance and impedance displays
out of the Smith Chart area.

Control over Design Elements -
The Short Circuit Stub control now has a more rational Up/Down
control. It starts at 90 degrees length and goes to zero length. The
counter reading and the separate electrical degrees display now agree
with one another. All 3 transmission line controls now display
fractions of a wavelength in addition to the electrical degrees.

The Help File has been updated to cover all of the new features.

Previous Installation Problems Resolved -
Releases are packaged so that there should no longer be a problem
installing on any 32 bit versions of Windows - i.e., Win 98 or later.
See the list of download sites at the end of this file.

Awareness of Regional Options -
The program is now aware of the Regional Settings as set in the
Control Panel. Thus, European users will now see a comma as the
decimal separator instead of the period and will use the comma as the
decimal separator for data entry.

Transmission Line Database made user friendly -
The user can create or edit the Transmission Line Database as an ASCII
text file using any text editor, such as Notepad. Two pre-defined
Master Transmission Line Databases are supplied with the program - one
for Western Europe and one for USA. The appropriate database is to be
selected by the user at first use and saved. Afterwards, that database
will automatically be used unless the user chooses use a different
one. It is possible to create and save many different transmission
line databases.

An Auto-Erase feature has be added -
This feature allows the user to erase plotted points by backing up
over them. This feature is useful when the user overshoots the desired
value.

User Configuration Features Added -
In addition to the configuration of the transmission line characteristics and the open and short circuit stub impedances, the user can also configure:

- the Font used for displays.
- the Auto-Erase flag (turns Auto-Erase on or off)
- the width of the points in Auto-Erase mode

Saving the Configuration -
The configuration is now saved in an INI file whenever the user chooses to save the configuration. The INI file initializes the program with the user saved configuration at each start up. The configuration items that are saved include the following:

- Font
- Auto-Erase flag and the width of the plot points in Auto-Erase mode
- Transmission Line Database Filename
- Line velocity factor, characteristic impedance and Frequency
- Stub termination resistance, capacitance and inductance

New Tools -
The Tool set now includes a tool for adding another Transmission Line Type to the Transmission Line Database. The tool accepts two points on the attenuation versus frequency curve and converts that to coefficients, "a" and "k" used in the transmission line database. The user also enters a velocity factor, characteristic impedance, Ro, and a description. The tool appends a new record to the user specified database or starts a new database.

Plotting Package -
The plotting package, NetworkProcessor, which is designed specifically to support SmartSmith, has been upgraded (as of 2/9/2005) to include SWR plotting (in addition to both magnitude and phase angle of Voltage, Current and Impedance).

Packaging -
The download packages are as follows:
SmartSmith and the Plotting Package, NetworkProcessor, are now packaged together as a single installation kit.
Network Processor (the plotting package), is also available as a separate package from the f20 site and the qsl site.

Download Site:
http://zaffora.f2o.org/W9DMK/W9dmk.html
High Speed Download Site:
http://64.217.230.66
Limited Site:
http://www.qsl.net/w9dmk (this site has NetworkProcessor plotting package and other free software offerings but does not have SmartSmith)

To quibble a bit more, the "Little Boy" uranium atomic bomb dropped on
Hiroshima weighed about four to five tons and was the equivalent of about
10 to 15 kilotons of conventional (TNT) explosives. The "Fat Man"
plutonium bomb dropped on Nagasaki had the equivalent of about 20 to 22
kilotons of conventional explosives. The variance in numbers is based on
quotes from different sources.

UNLESS you're working through repeaters and live in the valleys of a mountainous area. Then you're working bounces and if you get too high (high off the ground, but not as high as the hilltops around you), you can get up out of the signal.

2376. Tv antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-14 07:22:19 UTC

I have a Radio Shack roof top antenna, I bought about five years ago, it still works great.

It's a long range antenna, model vu 210, the best one they made, but they don't make it anymore.

I had a similar antenna about thirty years ago, it seemed to have a longer range

I lived in rural upstate New York lots of mountains, but I could get stations as far away as 141 miles, namely Ottawa and stations 75 miles away like Montreal.

But here in the Chicago area flat terrain and the same hight, I get Milwaukee very clear, but nowhere near the range I got years ago.

I have a theory, that it might be that the flat 300 ohm wire used in those days had better reception, and I know a lot more interference.

Right now I am using rg6 quadshield cable and have a high end booster connected.

Is my theory correct about the wire?

2377. Re: Tv antennas

Source record: 82116

A few possible reasons;

- 300 ohm ribbon certainly has less loss than RG6 but given you have a masthead preamp (booster) this is a mute point (The main idea of the preamp being to overcome line losses)
- The propogation conditions (inversions and bending etc) may have been better around NY than IL. Maybe the terrain helped too (eg knife edge) I wouldnt know though cause I am on the other side of the world!
- The general noise floor in the TV band has no doubt risen over the years with a lot more transmitters and general frequency use. In other words your TV may be able to resolve a low signal but it is blanked out by general band noise. We just did a test in the Melbourne CBD on the noise floor on VHF pager freqs. -76dBm was quite normal. The pagers work down to about -102dBm but with the noise that high are severely limited.

The noise floor problem is very hard to beat. You can point the antenna to reduce the noise from a known direction, using it to null interference rather than get max signal from the TV transmitter. Of course if the noise is all around you you are kind of stuffed!

- Your masthead preamp maybe being overloaded by strong signals and swamping the TV receiver. This will also serve to reduce the apparent sensitivity.

Selecting a preamp with good dynamic range or tuning specific to the station you want to watch may help. Realise though that these are commercial devices priced accordingly. If it has the capability try reducing the gain of the preamp and see if it improves things. You may also be able to purpose build an antenna for a particular frequency (tuned for gain and f/b etc) but this may not actually help. It all depends on how important it is to you!

Cheers Bob VK2YQA

I also used to live in NNY, Potsdam, and did quite a bit of 2m and 6m weak signal work, as well as the obligatory FM. The St Lawrence Valley plus the ducting from all the moisture from Lake Ontario are most of what you were seeing. You could often trip the Watertown W2WLR repeater from Ottawa with a handheld in a modestly tall building, say 4 stories. Ottawa (CHEZ ?) and Montreal (CHOM, as I remember) FM broadcast were audible over all of St Lawrence County, and well into Jefferson County most of the time on a car radio.

Jason:

Now that you have been directed to the theoretical discussion, let me alert you to some of the practical problems in
doing these measurements. Because of the very nature of the effect to be measured, the dynamic range required of the
test equipment approaches and sometimes exceeds the limits of even the very most expensive laboratory equipment.
Getting accurate measurements using average grade equipment requires a lot of caution, novel approaches, and it is often
simply not possible to make measurements with accuracy and repeatability of better then +/- 3 dB. Some quick examples:
power summers (dividers) are non-linear, intermodulation occurs in the most unexpected places, filters are either too
lossy or too broad, and so on.

Source record: 82119

Thank you for the comment about power line noise. Fortunately I live in an area with underground power. There can still be problems, of course, but single-point power arcing *usually* has a fairly distinctive sound.

Several direct replies to me indicate that other people have had the same experience that low-band noise is greater now than in the good old days. Perhaps it is simply the cumulative effect of many small sources.

Implied in my question about small receiving loops is whether they are less sensitive to this type of noise. (A dipole is often less sensitive to noise than a vertical when storms are around; is there a somewhat similar noise rejection effect with small loops?)

I realize that a small loop will produce lower level output than a larger loop (or other antenna) but, provided the S/N is good then either the receiver gain or a front end amplifier should take care of the level.

I am not attempting to compare a loop with a Beverage or other exotic antennas. I am attempting to compare it with a relatively low dipole or a simple vertical.

Thus far, replies indicate that basement operation is not very practical and that elevation does not help much.
Does anyone have A:B comparisons with simple dipoles and verticals?
Subjective comparisons are fine if they are based on real experiences.

One can also have a problem with height if the get so high as to key
multiple repeaters on a common frequency. While this is more commonly
a problem with aeronautical mobile stations, it also happens around
here for stations on hills between several repeaters or whose beams
line up with more than one repeater.

I have run into this when hiking, and operating from various summits.
I keyed up a repeater in Boston from the summit of Mt. Monadnock
(southern NH) and also got a repeater on the same frequency in CT.

Hi,

Here are a few links for you,

Build this one for a few dollars or free if you have the items at the shop.

http://www.eham.net/articles/7005

http://www.ac6v.com/antprojects.htm#2M

for coax, rg-58 just fine for short run in the truck,
just run the coax out the back of the cab same way
the taillight wires pass from the back of the cab at
the rubber gromet.

Mount the antenna on a 2x4 and slip in in the stake pocket.
Take it down or perhaps the xyl won't notice it ! ha ha.

Welcome to 2m !

Hi Group,

I have a older 5/8 wave 6m vertical base antenna. It has a tuning ring down at the bottom for SWR adjustment and it does not have any radials.

Anyone know who the manufacturer and model number?

Also, the fact that it does not have radials an issue? Should I add them?

The SWR is pretty good.

I suspect you have a Cushcraft 6M 1/2 wave AR-6 Ringo

If so the manual is on their site
http://www.cushcraft.com/support/pdf/951285.pdf

And NO don't add radials for this model -- it is self contained

BINGO! And, because it is essentually an end fed dipole, it
does not require radials for a counter-poise. As info, Jim NN7K

2393. Confused About Noise Floor and Sensitivity

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-14 20:02:01 UTC
From: Al <ABurzynski@nojunk.satx.rr.com>
Message-ID: <Zs7Qd.56315$uL5.24565@fe2.texas.rr.com>
Source record: 82032

In QST Jan 2000 the ARRL published some specifications about receivers including the Icom R75. Regarding the R75 it stated that the Noise Floor (mds) is -130dBm under certain specific conditions. It also states that the AM Sensitivity, 10dB (S + N)/N, under the same conditions is 1.7uV.

I am trying to equate the two specs into the same units. -130dBm is equal to 0.071uV; 1.7uV is equal to -102.5dBm. That is a difference of 27.5dB.

It is my understanding (and this is where the fault probably lies) that 10dB above the noise floor should put the signal at -120dBm, which is 0.22uV not 1.7uV. They are putting the signal at -102.5dBm. Where is the extra 17.5dB loss coming from? Doesn't 10dB (S + N)/N mean 10dB above the noise?

All input is greatly appreciated. Thank you.

Al KA5JGV

Manual tuners tend to have a much wider range of conditions under which they
can achieve a match.

Seems unlikely. If anything, the quality would have been worse in
"the good ol' days."

True it probably wasn't as good as I remember it, after all the picture
was black and white, and I settled for less back then.

Even now when I watch video tapes I recorded twenty years ago, before
cable. I could not believe I settled for that kind of reception.

But I do remember getting a strong signal from stations far away, the
only time I get that now is when there is a thunderstorm in the area.

I have had cable since 1990, Iove the technology of tv, not
necessarily the programming that is on it, that is why am messing
around with antennas and so on.

I primarily use it for fm and back up if cable goes off.

Hi Dan,

That's how it works here in Seattle for some. We have a lot of hills
that hide repeater antennas. We also have a lot of mountains that
reflect them (even from the opposite angle).

I was wondering, aside from the obvious , what the trade-offs might be between a moderately priced manual tuner (example: Palstar AT1KM) and a auto tuner such as the LDG AT-100 Pro or the soon to be released AT-200 Pro

I guess it is obvious that you have more control with the manual tuner and are more likely to achieve a match with minimal inductance..(or losses)

Not famliar enough with these auto tuners to know if that try to replicate a low-loss match that you can genarally achieve with a manual tuner or not.....

Would appreciate any helpful comments

>east of us is an idealized vertical mountain wall? Thus no hurry to
>upgrade to a yagi?

My guess - the mountains reflect some of the signal, but in a rather unpredictable manner and with much of the energy being reflected upwards.

The mountain reflections might help fill in a few gaps in your coverage pattern. However, the reflections are likely to _hurt_ coverage in some areas, due to multipath interference with the direct (non-reflected) signal. You might find that your signal suffers from a greater amount of picket-fencing due to multipath, than it would if the mountains were not present or if the antenna's pattern didn't include the mountains. The more vertical (and the more reflective) the mountain wall is, the stronger the reflections, and perhaps the more pronounced the picket-fencing.

It might well be worth your while to experiment with a simple somewhat-directional antenna. A single reflector, located perhaps .1 to .2 wavelengths on the mountainside side (sorry :-) of your current vertical, cut to perhaps 5% longer than a half-wavelength, could be used to shape your antenna's pattern into something vaguely cardioid. This would send your transmit energy (and your receive sensitivity) where it will do you the most good. Play around with the antenna-to-reflector spacing and see what it does to your pattern.

noise
> rejection effect with small loops?)

No. Actually, I don't even agree that a dipole is any quieter than
a vertical. It just depends on the polarization of the noise which
is best...You'll get about a 20 db attenuation of any signal, if the
polarization is 90 degrees out from another antenna....

>
> I realize that a small loop will produce lower level output than a
larger
> loop (or other antenna) but, provided the S/N is good then either the

There is no magic noise reduction using a small loop in general. But
you will see a tighter bandwidth compared to a larger antenna, and that

can act to reduce some noise. The Q will depend on the dia of the wire,
etc..
The real advantage to a small loop is it's sharp nulls, and the ability
to set it up to be easily turned. I suppose you could use very small
dipoles,
or verticals as the elements, but I don't see any change in s/n between

them. Naturally, the verticals would need some kind of phasing device
to
steer...You could turn the mini dipole indoors I suppose..."pre-amp
needed
I would think". But I don't know which would have the sharper nulls,
the
small dipole, or the small loop. In theory, I don't think should be
that
much difference...A larger small loop does have a better s/n ratio than
a
smaller, small loop, but you have to be in a quiet QTH to take
advantage
of it...IE: the lower the atmospheric and local noise, the more
advantage

to a larger loop. If the noise is high, IE: summer, often the smaller loops work about as well as the larger ones...
>
> I am not attempting to compare a loop with a Beverage or other exotic
> antennas. I am attempting to compare it with a relatively low dipole or a
> simple vertical.

Well, if you mean full size low dipoles, and verticals, of course, the nulls on the small loop would be much better, and more useful as far as

nulling a noise source.
>
> Thus far, replies indicate that basement operation is not very practical and
> that elevation does not help much.
> Does anyone have A:B comparisons with simple dipoles and verticals?

Sure...Do it all the time.....If I'm on MW, I prefer
the small loop over any of the usual wire antennas...
On 160, depends...There, I actually listen on my transmit antenna more than the small loops...IE: DX...DX will often come in better on a vertical, than the small loops, I think just due to the polarization...
My small loops are horizontal...IE: diamond, fed at the bottom...
I have an inv L, and also a top loaded vertical on 160, so it's probably not unusual to hear some dx better on those, than the loop.
I also have a Z dipole on 160....
My loops are mainly for MW and LW....On 160, it's a toss which is best...The loop is often good for ragchew listening...

Outside of being cartoons, if you mount a vhf or above antenna on your hat
you will usually gain some range. If you put a HT on your belt the antenna
is against your body and use a speaker/mic most of the signal is abosrbed
you your body. By placing the antenna on your hat you gain height and don't
have your body in the way.

No one really angry, but a few people in Boston were confused when
they only heard my side of the conversation with the ham in CT,
although there was no other traffic on the Boston repeater. Only the
Boston repeater has tone, the other one doesn't.

I have also seen some areas deal with tone added for intermod control
by having all of the repeaters in the area (coastal Maine for example)
use the same CTSCC tone. This simplified things for hams with older
equipment.

Happy trails,

You could use RG-59 for everything except the DVD player - that could
use either composite, component or S-video.

Since you don't have audio video inputs on your tv you need and rf
converter
here is a link for what you need and details of how it works. It's
about 50 dollars but worth it.

http://www.radioshack.com/product.asp?catalog%5Fname=CTLG&category%5Fname=CTLG%5F003%5F010%5F011%5F000&product%5Fid=15%2D1988

From: Ivan Makarov <miv@hotmail.com>
Message-ID: <VMudneVWEOOi9ozfRVn-oA@rogers.com>
Source record: 82056

Jon,

I bet what you experiencing now is stray RF triggering either the tuner or the radio. Because 706 has CMOS at its control circuits, this does not have to be a strong RF signal, may be your local broadcast station or your 802.11 router will induce enough energy into the cable to trigger the circuit. If you removed the ferrite beads from your cable, put them back on. To improve noise suppression make a turn or two through the beads. If the hole diameter is not big enough, put one more bead. Locate the beads near the unit. If you can not replace your TP cable with a shielded one, I would suggest to connect one wire of each TP to the ground. You asked how come the Ethernet works fine with TP - you can not compare these things. Ethernet transciever may use differential input amplifiers which supress common mode noise by design, noise-immune modulation and different voltage swing. In your case it is a single ended control wire, so all induced noise will get inside the radio. If you can, put 0.01 uF bypass capacitors from the control wires to the ground at the transciever side. I read AH-4 has chokes inside, so concentrate youe efforts on the transciever side. The transciever may also have some noise supressors inside, but people's experience with the remote head control cable shows they are not effective enough. Sometimes Icom does weird things. One of them is about the remote head control cable, First, at the remote head side its shield is not connected to anything. Second, at the transciever side, its shield is electrically connected to the enclosure through a black oxidized screw, which , if not tightened enough, works as an insulator, because it is made of an oxideized material. Look at yours by the way. I replace that screw with a stainless steel one. This is the thing to look at if you use the head remotely. When the head is sitting at the unit, it works OK. Sorry for a bit of an off-topic..

Good luck with your troubleshooting,
Ivan

Here's how I've had them hooked up at my QTH:

Assuming sufficient signal strength at the antenna for decent picture to begin with:

RG6 or RG59 cable connects to TV antenna via weatherproof transformer. Other end of Cable feeds the VCR (Antenna Input), with the DVD player feeding the VCR via the analog composite video and audio signals (rca jacks marked composite input or Aux. Red/white are audio, yellow is video)

Output of the VCR (marked TV) feeds the antenna signal amplifier, which has a splitter (or multiple outlets) that feed cables to local TV set and several other rooms.

Works great. Local channels can be tuned by VCR and sent out on Channel 3 or 4, or Passed through for each set to choose it's own channel. In VCR mode, you can select the Aux Video and the DVD plays on the TV. With a splitter after (or part of the amplifier) every TV in the house sees the same signal, so with multiple sets on, you can move from room to room and not miss much of your "favorite" program.

If you are in a "far fringe" area, and signal strength at the antenna isn't all that great, you may also need along with having an antenna mounted signal amplifier between the antenna and the cable (at the antenna end). This will mean you also have a power injector (part of the remote signal amplifier) before the VCR. However, bear in mind that if you don't have a good signal to begin with, you will be amplifying noise along with the signal and you may not get much better than without the remote amplifier. In this case, you really need to get a satellite dish and subscribe to local networks if you can.

It is not a good idea to to connect the dvd player through the input of the vcr, many dvd's are copyguarded which creates a bad picture, when played via the vcr inputs.

Al> From: "Al" <ABurzynski@nojunk.satx.rr.com>
Al> Xref: aeinews rec.radio.amateur.antenna:5148

Al> In QST Jan 2000 the ARRL published some specifications about receivers
Al> including the Icom R75. Regarding the R75 it stated that the Noise
Al> Floor (mds) is -130dBm under certain specific conditions. It also
Al> states that the AM Sensitivity, 10dB (S + N)/N, under the same
Al> conditions is 1.7uV.
Al> I am trying to equate the two specs into the same units. -130dBm is
Al> equal to 0.071uV; 1.7uV is equal to -102.5dBm. That is a difference of
Al> 27.5dB.
Al> It is my understanding (and this is where the fault probably lies)
Al> that 10dB above the noise floor should put the signal at -120dBm,
Al> which is 0.22uV not 1.7uV. They are putting the signal at -102.5dBm.
Al> Where is the extra 17.5dB loss coming from? Doesn't 10dB (S + N)/N
Al> mean 10dB above the noise?
Al> All input is greatly appreciated. Thank you.

Al> Al KA5JGV

I think it's a typo I calculated 0.775uV not 1.7uV. They might have
added a 1 in front of the decimal instead of a zero.

It will not work as a rediating antenna. I bet this setup could be incorporated into an antenna system somehow though. We have some pretty sharp dudes in this group so if it's possibel that it will assist some type of antenna, this is the place to monitor.

The noise floor from Boltzmannian theory is, ISTR, -174dBm/Hz.

That is, per Hz of Bandwith.

Therefore, 3.4 kHz of BW will give you an increase of +35.3 dB,
giving you theoretical a noise floor of -138.7dBm, which you must
then degrade by the noise contributions from the RX itself.

$$

Parents of 15 year old find $71,000 in CASH in closet!

$$

Does this headline look familiar? Of course it does. You most likely have just seen this story recently featured on a major nightly news program (USA).

His mother was cleaning and putting laundry away when she came across a large brown paper bag that was suspiciously buried beneath some clothes and a skateboard in the back of her son's closet. Nothing could have prepared her for the shock she got when she opened the bag and found it was full of cash. Five dollar bills, twenties, fifties and hundreds- all neatly rubber-banded in labeled piles. "My first thought was that he had robbed a bank", says the 41-year-old woman, "There was over $71,000 dollars in that bag- that's more than my husband earns in a year."

The woman immediately called her husband at the car-dealership where he worked to tell him what she'd discovered. He came home right away and they drove thogether to the boy's school and picked him up. Little did they suspect that where the money came from was more shocking than actually finding it in the closet.

As it turns out, the boy had been sending out via E-mail on the internet a type of 'chain-letter' to E-mail addresses that he obtained off of the internet. Everyday after school for the past 2 months, he had been doing this right on his computer in his bedroom.

"I just got the E-mail one day and I figured what the heck, I put my name on it like the instructions said and I started sending it out", says the clever 15-year-old.

The E-mail letter listed 3 addresses and contained instructions to send one $5 dollar bill to the person at the top of the list, then delete that address and move the other 2 addresses up, and finally to add your name to the bottom of the list. The letter goes on to state that you would receive several thousand dollars in 5$ dollar bills within 2 weeks if you sent out the letter with your name at the bottom of the 3-address list "I get junk E-mail all the time, and I really didn't think it was gonna work", the boy continues.

Within the first few days of sending out the E-mail, the Post Office Box that his parents had gotten for his video-game magazine subscriptions began to fill up with not magazines, but envelopes

containing $5 dollar bills. "about a week later I rode (my bike) down to the post office and my box had 1 magazine and about 300 envelopes stuffed in it. There was a yellow slip that said I had to go up to the (post office) counter- I thought I was in trouble or something (laughs)". He goes on, "I went up to the counter and they had a whole box of more mail for me. I had to ride back home and empty out my backpack 'cause I couldn't carry it all".

Over the next few weeks, the boy continued sending out the E-mail. "The money just kept coming in and I just kept sorting it and stashing it in the closet, I barely had time for my homework". He had also been riding his bike to several of the area's banks and exchanging the $5 bills for twenties, fifties and hundreds. "I didn't want the banks to get suspicious so I kept riding to different banks with like five thousand at a time in my backpack. I would usually tell the lady at the bank counter that my dad had sent me in (to exchange the money) and he was outside waiting for me. One time the lady gave me a really strange look and told me that she wouldn't be able to do it for me and my dad would have to come in and do it, but I just rode to the next bank down the street (laughs)".

Surprisingly, the boy didn't have any reason to be afraid. The reporting news team examined and investigated the so-called 'chain-letter' the boy was sending out and found that it wasn't a chain-letter at all. In fact, it was completely legal according to US Postal and Lottery Laws, Title 18, Section 1302 and 1341, or Title 18, Section 3005 in the US code, also in the code of federal regulations, Volume 16, Sections 255 and 436, which states a product or service must be exchanged for money received.

Every five dollar bill that he received contained a little note that read, "Please add me to your mailing list". This simple note made the letter legal because he was exchanging a service (adding the purchasers name to his mailing list) for a five dollar fee. Here is the letter that the 15-year-old was sending out by E-mail, you can do the exact same thing he was doing, simply by following the instructions in the letter.

Here are instructions on how to make $10,000 US cash in the next 2 weeks:

There are 3 addresses listed below.

Send the person at the top of the list a $5 bill wrapped in 2 pieces of paper (to securely hide it), along with a note that says: "Please add me to your list".

Then delete that name, move the other 2 up and put your name at the bottom.

Now start sending this ENTIRE E-mail back out to people. When 20
people receive it, those 20 people will move your name up to the
middle position and they will each send out 20. That totals 400
people that will receive this letter with your name in the middle.
Then, those 400 people will move your name to the top and they will
each sen you a $5 bill.

8,000 people each sending you a $5 bill = $40,000 cash. That's if
everyone responds to this E-mail, but not everyone will, so you can
expect more realistically to receive about $10,000 cash $5 bills in
your mailbox.

This will work for anyone, anywhere in the world in any country, but
send only a US CASH $5 bill.

The more E-mails you send out, the more cash you will receive. If
each person sends out 100 E-mails, there will be 1,000,000 people that
receive this letter when your name reaches the top. If only 1% of
those people respond, you will get $50,000 cash.

Here is the list:
---

1) A Wyrick
1628 Silverlake
Centerville, Oh 45458

2) Enrique Martinez
2427 N Avenue
National City, CA 91950

3)Lorenzo Sadler
3908 yorkland dr
comstockpark, 49321

THERE'S NOTHING MORE TO DO! When your name reaches the top in a few
days, you will start receiveing $5 bills from other people just like
yourself, who are willing to invest a $5 bill to receive $10,000 cash.

If you don't try it-you will never know!

How would I go about making a cheap, easy cb antenna for a base station at my house? How far would it need to be from my 2 meter antenna?

Could I make a whip by cutting an aluminum 3/8 rod to a 1/4 wave and thread the end to go into one of those 3/8-24 so239 mounts?

I was thinking about the radiation from the coax, myself, but
unless you run very high power, not that much of a concern
Reason would be more to prevent stray rf into power supplies,
ect. (rf in voltage regulator circuits can have some very
undesired effects), but the change in the pattern should be
minimal. What DOES concern me, however (I ran one in beacon
service for many years) is that they dont seem to like EXTREME
WEATHER! If you are in a normal location, then it is no problem.
If, like where my 6 meter beacon was located, is at 8,000 feet,
surrounded with winds up to 125 M.P.H., and heavy iceing, then this
antenna will be a stub in a few weeks, at most! Lost 2 of them in 6
weeks , finally brought it down to reasonable location, useing
stealth antenna to hide it. Not the coverage but not replaceing
antennas all the time , either! For what it is, (a vertical dipole),
I'll give the devil its due-- it actually does work pretty well, with-
out excessive claims as to its capabilities! Jim NN7K

There has been a fair amount of research on this. In Canada, your Basic Qualification test may, in fact, contain questions based on information from Health Canada's /Limits of Human Exposure to Radiofrequency Electromagnetic Fields in the Frequency Range from 3 kHz to 300 GHz, Safety Code 6/ (<http://www.hc-sc.gc.ca/hecs-sesc/ccrpb/publication/99ehd237/toc.htm>.) At least the parts of this document that pertain to the Amateur Bands allocated to Amateurs in Canada.

I'm guessing there are similar government or private bodies around the world which have the same sorts of documents available.

This seems to boil down (pun not intended) to:

"Although not a requirement of the Code, it is suggested that whenever possible, the organ-averaged SAR for the eye not exceed 0.4 W/kg. As stated in Appendix VII, this suggestion shall remain until sufficient scientific information is available to accurately assess the health effects of RF exposure on the eye."

Translation: when working with reasonable powered RF transmitting devices, especially at higher frequencies, minimize exposure to your eyes.

Apparently, this is something they want amateurs to remember, because this is directly related to a few of the questions in the Basic Qualification question bank.

I read somewhere that some amateurs cringe when they see VHF/UHF amateurs wandering around at ham events wearing head-mounted mobile units, not unlike your hardhat rig. I suppose a QRP rig would be no

worse than a mobile phone.

Of course, I have been thinking about getting a headset for /that/.

I was going to ask if it would be OK to perch my 2 meter vertical antenna in the branches of a tree, or will nearby limbs detract from the signal, but I see http://www.preservedpalm.net/gsm.shtml "The product used in Palm antennas is formed by the tree itself and the fronds", but perhaps that only applies at those higher frequencies.

Hello,

I've been searching for an answer to this question for years. I'm hoping somebody here can answer it or at least point me in the direction. Or maybe I'm totally off base on my basic understanding and so this question is out in left field.

I've been to howstuffworks.com and read a few articles on radio; I learned a few cool things, but not what I was after.

Here's my question. When a radio tower, or whatever, sends out a wave it has to propagate somehow. I figure this works by making electrons do their thing, vibrate or whatever those crazy nothings do. If a group of electrons is creating a field or sending a wave it has to be at a specific frequency, but what I don't understand is how can there be the plethora of frequencies all at the same time in the same place? Can't an electron only vibrate at one frequency at a time? In simple terms: how can my radio have the potential to tune into all the stations; how do the waves not interfere with each other?

In wave theory, in physics class, I remember sending one water wave from one end, and another from another end, and they cancelled each other out. Wouldn't a radio wave work the same way?

So many questions, so little time...

Thanks,
Bodi

Hi Bodi,

Let's start without electrons, but limit ourselves to how a "message"
propagates: You are in a theater waiting for your friend that you
have saved a seat for. You see your friend come in, you wave. Your
friend sees you, and waves back.

Now, a message has propagated and no power was transferred. You
didn't have to move any electrons to do it and we needn't go into the
discussion of light waves and interference or any of that to explain
it either.

A radio tower doesn't work this way, so now we can investigate what is
all that power for? It is not to push electrons at you or to suck
them either (one has to account for both directions in AC). But it
does have to do with attracting or repelling what electrons you do
have (if you didn't have any, believe me, you would never get to see
South Park on TV).

The attraction and the repulsion is a Force that is propagated. It
happens to have a frequency (or vibration as you describe).

>Can't an electron only vibrate at one frequency at a time?

Dangerous question, because, yes it can; but rarely does this have to
do with anything practical. It is properly known as a de Broglie wave
and it exists in every material object, but it is very remote from RF.

>In simple terms: how can my radio have the potential to tune into all the stations;

This is called resonance and Q: the ability to select one from many.

>how do the waves not interfere with each other?

The same way you can hear a conversation in a crowd. Interest in the
topic is resonance, interest in the speaker is Q. If you are only
mildly interested in the speaker, other speakers will divert you. If
you are only interested in the speaker, then the resonance is probably

romantic (and has nothing to do with topic of conversation).

>In wave theory, in physics class, I remember sending one water wave
>from one end, and another from another end, and they cancelled each
>other out.

Your recollection is rather hazy, or you have not described the
complete experiment.

> Wouldn't a radio wave work the same way?

It didn't work that way in the first place.

When you speak of cancellation, you must first intrude yourself or a
proxy for yourself into the situation, otherwise nothing "happens."
That proxy is often a detector (in the form of a load with a meter) or
your eye (another detector with a load), or your ear (guess what?
another detector...), or....

Just a few simple thoughts (;-)
Two folks talk at the same time
A listener hears both without interference NOTE1
Repeat for a telephone - same result
Electromagnetic waves work in a similar fashion
Key here is signals don't mix or interfere in a linear device or media

NOTE 1: the above doesn't work if one of the speakers is your mother-in-law
(;-)

Separation of signals is done with selective circuits -- tune to 14.200 MHz
and the selective circuits rejects all the others.
The human ear can do this -- I never hear my mother-in-law

Suspect this will get the flames (;-(

I had a variety of wire and "experimental" antennas fed to a remote switch then down to the manual tuner in the shack. With the bands being what they have been lately, I was doing a lot of band hopping which required a lot of knob twiddling. I have since purchased an Icom AH-4 remote tuner (to go with my IC718) and installed a 75 foot loop in the attic with the AH-4 at the feed point. Using the cable that went to the antenna switch, I now just press a button on the rig and the tuner has a better then 1.5:1 match in less then 2 seconds. Much easier. Your mileage may vary.....

D> vaguely cardioid.

Yes! Say, can one just cut the reflector 5% longer than the antenna?
The antenna is some complex double 5/8 wavelength job.
If the reflector is shorter than the antenna, it becomes a director?
What if the reflector is just a pole jabbed into the ground, thus
grounded and longer downwards than the 5%? What if the pole is "very
much longer than the antenna in both directions"?
How about the thickness of the reflector? Only as thick as the antenna
itself (but wait, the antenna has two thicknesses, top thin, bottom
thick), or just grab any iron pipe (wait, metal type and shape
important?)

Bondi wrote:
"---but what I don`t understand is how can there be a plethora of frequencies all at the same time in the same place?"

In a linear system or medium, individual frequencies don`t mix, but they coexist without affecting each other. They "superpose".

The superposition theorem says that when any number of frequencies are applied to the linear network simultaneously, their combined voltage and current are the sums of their components as if the individual components had acted alone.

An antenna can deliver many frequencies to a receiver which can select, by using a proper filter, the desired frequency.

A radio wave consists of equal-enengy electric and magnetic fields. Each field generates the other. These fields travel through the complete void of deep space where there are few or no electrons to be excited by the waves.

Sunlight is an electromagntic radiation, much like a radio wave but of higher frequency. It is composed of many colors (frequencies) which may be separated. Taken together, the colors are perceived as white light.

Bodi also recalled waves from opposite ends of a water tank cancelling. That happens at some places, but they reinforce at other places. Radio waves cancel and reinforce too. However, radio waves traveling in opposite directions rarely affect each other`s progress, and they pass through each other as if the other never existed.. The summation of two waves at any particular point may be vastly different from their summation at a different point.

Traveling waves of the same freuency can produce stationary interference patterns called "standing waves".

Waves in far space don`t propagate by causing a group of electrons out there to vibrate. The wave`s electric field changes according to its cycle and this change generates a magnetic field and vice versa.

Best regards, Richard Harrison, KB5WZI

2439. trees are nature's towers and antenna combined

Hey all,

I'd have posted this somewhere else but couldn't find a group more suited. I've just got run-of-the-mill 2.45ghz bluetooth dongle and frustrated with its range ripped off its cover to find a wonderfully custom pcb inside. Anyways, theres a small surface mount component inside labelled "ANT1", reading a resistance of practically nil and ditto for capacitance. I'm assuming it to be the antenna. Anybody know of a way I could stick a transistor on it or something to boost the range (I'm not all too experienced with radio I'm afraid so that might sound stupid) - or just peel it off and replace it with a few peices of wire or something.

Sorry for sounding stupid and thanks in advance,

Josh

Not the way I read it.

It appears to be nothing but a clever camoflage of the actual GSM
antenna. The preserved tree and fronds just happen to make an adequate
support system and do not significatnly degrade the actual GSM
antennas while hiding them from view.

However, if they can do it, you should be able to as well.

>important?)

Well, I think you'd probably need to do a bunch of modelling in NEC2
or similar to get a really solid analysis, for any given antenna and
reflector.

The "5% longer" rule of thumb applies to antennas which use halfwave
radiators - it works with Yagis, and Cebik has an analysis which
indicates that it works with Yagi-like beams based on vertical J-poles.

I suspect that the issue is rather more complicated for antennas which
use 5/8-wave or stacked/collinear radiators. The phase relationships
between driven and parasitic elements in such antennas are probably
different enough that this simple rule might not apply.

I believe that you could probably get a fairly effective
pattern-warping by using a non-tuned reflector which is significantly
longer than your collinear radiator. Try cutting a piece of EMT or
other conduit (or aluminum pole, or whatever) so that it's a few feet
longer than your antenna, and then install it 6" to a foot on the
undesired side of the radiator... have one end of it sticking up at
least a foot above the top of the radiator and the other extending
down below the bottom of the radiator.

Some commercial multi-bay stacked dipole antennas use the mast or
tower in just this fashion, to convert a circular omni pattern into a
cardioid or off-center near-circular pattern. Varying the antenna-to-
mast/tower spacing changes the shape of the pattern.

The really bad news for all us humans is that there has been no comprehensive understanding of electromagnetic radiation. We do not truly know what it is. This may not happen until there is a unified theory of how everything works, including gravity.

We know very well how to generator, transform, and receive electromagnetic waves but we just don't understand what they are.

Anyone who says they understand the complete physics of electromagentic energy is either full of BS or our next Einstein.

Sigh

His arrangment sounds a bit like a shunt-fed antenna tower. Perhaps
the "brushy" nature of the top of a tree makes it behave a bit like a
"fat" dipole, with the broad bandwidth the page speaks of?

One limitation of these is clear from the article - they're seasonal.
When winter comes and the sap is gone down into the roots, the
antenna's performance degrades quite badly.

Hmmm... I wonder... would QRO operation on a sugar maple in April
leave you with a bucket full of maple-flavored Fizzies?

I have a MFJ-993 auto tuner rated for 300 watts. The MFJ-994
autotuner is rated at 600 watts. If you compare them they are almost
identical. The 994 has slightly larger toroid inductors but the same
16 amp latching relays and cap ratings. The 993 has a few extras such
as small built in balun, LCD display, and dual antenna ports thus 1
extra relay, yet it is less expensive. I run my 993 into a 200 foot
flat top antenna fed with 50 feet ladder line to an external 4:1 balun
fed by 20 feet of 72 ohm co-ax from the tuner. It has a very wide
inductance and capacitance range so it tunes all bands 160 thru 10
meters extremely well. Thats an important feature to look at when
comparing tuners as some models have quite a limited range. Once a
full auto tune has been done on a particular frequency the next time
that frequency or one close to it is used it just snaps in the correct
relay settings in about 1/2 second for a match. It has many other
usefull features that I wont bore you with. The best part is it will
handle my 600 watt amp on SSB with no problem as I thought it would
after comparing it with the 994 but if you run a kilowatt or so its
not the one for you. Its wonderful when hopping around, no more
cranking and twiddling and QRMing the bands. And no it doesnt get hot
or even slightly warm so efficiency is well up there. My manual L
network tuner now sits in the corner. I dont suggest everyone over
power one as it may fail especially if you have a difficult load, but
it is conservatively rated and works well on my antenna.

Reg.
You asre concentrating on things that you can do nothing about
i.e.the ionisphere and trivialising the things that you CAN do something
about
which is TOA, the subject of this thread.

If the transmitting station TOA is low enough to make the QSO in one hop
and the receiving station antenna has a higher take off angle that requires
exactly two hops to reply then the paths are NOT the same.
I would also doubt that the paths taken when being bent by the reflecting
layers
would be the same as the density is subject to change
. The real discussion regarding TOA is to achieve a QSO
with one hop instead of two so as to cut down on travel losses and that is
where
the importance of TOA and associated angles that follow the +/- 3 db takes
place.
Regardless of the physical position of the antenna the elevation angle of
the radio wave
IS related to antenna construction.
Just a different view point Reg, the antenna I CAN do something about.
Natures actions
I can do NOTHING about except to have the correct equipment when good
conditions occur
and that is where TOA gains it importance.
In my designs I try to have the lowest contour of the bottom lobe even tho

it may mean
a loss of a db in gain at the actual TOA.and I do not concern myself with
the technical data
that your posting revolves about, which tho it may be interesting to some,
as I cannot change it
Nothing personal nor am I nitpicking
Cheers
Art

A hint: Make the loading coil part of the transmitter rather than part
of the antenna.
If every thing is built inside of a single metal box it should be OK.
Put this thing on top of a metal surfaced roof and ground your box to
the surface directly.
The 3 meter pipe should be very close to the box. Like 1 or 2 inches
and you have to subtract any lead length from the antenna size.

2454. OPEN WIRE LINE

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-16 03:44:34 UTC
From: me <nospam@nospam.com>
Message-ID: <hnf511559551ke2c6g7gf44ddv886vjhlv@4ax.com>
Source record: 81993

After many years of experimenting with coax fed wire antennas I am taking my first plunge at open wire line.

To get into shack, I need to go through exterior steel siding, exterior wood siding & plywood, a layer of insulation, then interior sheetrock and wood paneling. Assume I need about 4-6" of safe feedthrough so that standoffs can be mounted on the walls oustide and inside the shack.

I generally run 100 to 1500W output...at full legal limit probably 3KV on the feedline...am not crazy about the idea of setting my house on fire due to HV arc over.

Am looking for the old style porcelain feedthrough isnulators, but so far have not found same.

Local Home Depot has thin PVC tubing (as in sink/toilet stems), vinyl tubing, welding rod tubes, etc. What are the dielectric properties of these, and the high voltage breakdown voltage...???

Seems like glass, porcelain, or ceramic tubing would be best feedthrough insulator, but where to find?

Are any modern day materials found in Lowes or Home Depot safe from arcing and also efficient for RF?

Thanks in davance & 73,

Dan (K0DAN)

One thing I didn't see explicitly stated in the answers is that the progation of radio waves doesn't require electrons. It propagates just fine in space, or even an empty vacuum. Radio waves are of course the same sort of stuff (electromagnetic waves) as light, just a different frequency. So if electrons were required for propagation, the light from the Sun would never make it here.

Dear Dan,

It seems that many take the approach of using a pair of coax lines hooked up as a balanced coax pair as the answer to that problem. If you are worried about the impedance discontinuity, it's a short section and will not be a problem. If you are worried about whether or not the coax can handle it, RG-8 is good enough and RG-17 is better. If you want to combine a little bit of protection against near strikes while you're at it, run through the wall low to the ground and close to the biggest, best earthing system you can put together, and then connect the shields of the coax to a short hunk of heavy wire to that earthing system.

There must be NO metal and NO low-grade insulating material BETWEEN the pair
of wires as they come into the shack.

Bring the wires close together for a short distance through a relatively
small hole in the wall. At HF, the small lumped increase in capacitance
between the wires will have a neglible effect on system operation.
Equivalent to an unoticeable minor shift in tuner settings. No additional
line loss will be incurred.

Insulate the pair of wires from each other by using the inner conductors of
coax cable plus the polyethylene. Discard the outer conductor braid. To
minimise size of hole through the wall allow the polyethylene coverings to
touch each other if you like.

The main problem will be rain and weather-proofing.

For a short, indoors, distance to the transmitter or tuner, the twin
polyethylene insulated wires can be retained and allowed to separate if
convenient.

> be the plethora of frequencies all at the same time in the same place?

Free electrons are free (pun intended) to emit photons of any
frequency. Electrons that are not free are not free to emit photons
of any frequency. Superposition of EM waves is what makes it possible
for "the plethora of frequencies" to exist all at the same time in
the same place. The energy in an independent wave is, well,
independent of the energy in the other waves. A lot of hams don't
understand that the energy in the forward wave is independent of
the energy in the reflected wave and vice versa.

> Can't an electron only vibrate at one frequency at a time? In simple
> terms: how can my radio have the potential to tune into all the
> stations; how do the waves not interfere with each other?

Free electrons have the freedom to emit and absorb photons of any
and every frequency. Free electrons exist in conductors and can
travel from atom to atom or molecule to molecule as needed. The
electrons are the carriers of the EM waves, but not the EM waves,
much as water molecules are the carriers of ocean waves but are
not the waves.

Beg to differ. A certain amount of irradiance was decoded by
the retina of the receiver. Irradiance *is* power. Energy was
transferred and energy transfer is power, by definition. For
your statement to be correct, the event must be done in total
darkness.

fl> Sigh

I think I have an insight and I really don't think I'm very bright.
Basically light is the transfer of EM energy and information across a
distance. Energy is carried by the photon or quanta. Radio
transmissions are like light only at much lower frequencies. At radio
frequencies a very different method must be used to generate the
photons. Basically electrons are agitated the length of a wire at
its natural resonnance and the photons are shaken off as an
electromagnetic disturbance or field, then it propagates into free
space. Whatever modulation is impressed on the wavetrain is the
information being transmitted. What's so special about that? It may be
too simplistic but that's the way I picture it. How would you describe
it?

There is an alternating current in the antenna conductor which sets up magnetic and electric fields.

The field spreads out in space at the velocity of light. It can't help itself.

As the current in the antenna changes and alternates, the field more remote from the antenna becomes left behind in time and so becomes detached from the vicinity.

The detached field, pushed outwards from inside by newly generated alternating waves from the antenna, continues to expand into space at the velocity of light for ever more.

The keywords are Time, Velocity and Distance (or Wavelength).

And so you have it. It's really all very simple.

> If the reflector is shorter than the antenna, it becomes a director?

Nope, the reflector needs to be 5% longer than 1/2WL.
A 5/8WL antenna is NOT resonant. Passive elements must
be close to and referenced to resonance.

I had a vertical loop resonant on 17m. I installed a
reflector 1.05 x (1/2WL of 20m). It became a beam on 20m.

And that is true for forward and reflected waves in
a transmission line. They only affect each other at
an impedance discontinuity which causes reflections.

Passive non-resonant elements have very little effect.
That's what allows a lot of multi-band beams to work.

That's true, but we do understand the emission and
absorption of photons by free electrons. As Feynman
says: "A photon goes from place to place. An electron
goes from place to place. An electron emits or absorbs
a photon." This basically describes everything that
happens in a ham radio antenna system.

For that 6" run, just use two pieces of parallel
coax. The inside conductors are your balanced
conductors and the braids are grounded. Be sure
not to exceed the voltage rating of whatever coax
you choose to install.

The free electrons in a conductor (aluminum or copper) are
required for the emission of photons (EM waves) from ham
antennas during transmit. They are required for the absorption
of photons during receive. Free electrons are the carriers for
all of our localized ham RF activities. Once the photons have
been generated, they can travel through the "aether" without
having electrons present.

No offense, but where I live live the guys joke that they use the ringo ranger II as a fishing pole or dummy load. We haven't experienced a good one here. Anything else is far better in our experience and I know of no one actually using one now, but they say there's a stack of them avsailable for free behind a certain store.

No, there's nothing simple that someone not very experienced can do to extend the range. Your best bet is to try a physically bigger dongle that's likely to have a better antenna.

First off I don't really believe in one way propagaiton unless someone can convince me otherwise ? However, I am curious about a phenomenon I've experienced with a number or radios and antennas over the years. I've had eveything from a 4 element Yagi at 55 feet to the dipoles I'm using now and lots of new transcievers. I work all CW and on occasion I'll get a 599 signal report from the other station yet he's barely copyable from my end. They all seem to be running the same 100 watts or more that I'm using now and are using a dipole cut for the frequency in use like I am or a G5RV etc. I wonder if anyone else has observed this and/or has an explanation ? This has occured on new transceivers too numerous to name over the years. So I know its not a problem with a particular radio.

73 and Thanks in Advance

Source record: 82011

Aunwin, we are talking about two different things.

If I want to communicate (optimally) with another station it is important that I know the direction and elevation angle at which to point my antenna such that the radio beam preferentially returns to Earth in the vicinity of the other station.

Direction is found from a map of the Earth's surface plus a magnetic compass.

The ONLY way to find the elevation angle is to CALCULATE it from the ground path distance between the two stations, the height of the reflecting layer, and the number of hops along the path.

It's purely a matter of Spherical Geometry. It has nothing to do with where your antenna happens to be pointing. Or even whether or not you have an antenna.

All good radio engineers do it that way. Caculating formulae can be found in practical radio engineering books. Eznec won't tell you.

Use simple program TWOHOPS to do common calculations. Results are as accurate as the inevitably uncertain input data.

No offense taken....
Where I live we use bamboo for fishing and Ringo Ranger II's for distant vhf communications. Perhaps you have it mixed up where you live. Take the coax off the bamboo and hook it back to the Ringo....

You don't by any chance have a window close at hand that you could run the
feeders through?
This really simplifies the situation. That is the way I get my feeder in and
out of the house.

Why are the ones you buy dont have ground radials. Like the "sticks"
they use on trucks?

I am guessing they are 5/8 wavelength and have some sort of coil inside
them I cant see.

I am not wanting "super performance" But something that is decent.

I also wonder what all this would do to the tree. While it wouldn't be
such a big deal in the woods, I wouldn't want to kill the trees in my yard.

I am going to take a stab at this.
I would think that the 5% greater than the 1/2 wave will be a better
reflector than the 5% greater than 5/8 wave. I am thinking that the
wavelength of the signal is what we are dealing with more than the
size of the transmission element.

I did a very non-scientific experiments with rubber duck antennas and
beam elements many years ago. One of the tricks I used was to put a
rubber duck between the reflector and driven elements of a small beam.
The signal improved radically. I also tried it with three rubber duck
antennas. The reflector duck had an extension to make it a little
longer. The change in the signal strength was, as expected, a little
improved, but not greatly.

I also placed a 5/8 wave j-pole between the reflector and director.
It produced a better signal than the rubber duck did, but not as much
as I had expected. I didn't go any farther with the experiment. I
didn't keep a log or use calibrated equipment or anything. Like I
said, I was just playing around with it a few minutes.

The metal truck is the "ground plane". If you had
a copper roof, you wouldn't need radials.

I use ceramic feedthrough insulators on a piece of board in the bottom
of my window to bring 450-ohm line indoors. I got the insulators from
Surplus Sales of Nebraska -- you can check their web site for info;
they have a pretty good selection of NOS in all sizes, tho' they ain't
cheap.

You may do just as well rigging something else, as per some of the
other suggestions here...

Excellent idea...I can envision a couple N or UHF connectors on either
side of the wall, and the entry point is indeed near the ground system
so that too is feasible. Thanks for the tip...there are others coming
in but this sounds very feasible and relatively easy!

Hi Cecil...

Vote #3 for the coax feedthrough...sounds like this trick is well
known and escaped all my reading.

Thanks and 73

You both might be interested in knowing that you are compairing apples
and oranges-- as the Ringo is VERTICAL polarized, while the M2 is
HORIZONTAL polarized-- makeing a 20 dB difference at the recieved
end - the advantage of either one depending on the polarization of the
recieveing antenna! -- Verticals for FM, Horizontals for C.W /S.S.B.

Ed...

Nope, the window is not feasible. There is an awning type window with
metal frame but its location and installation make it unfeasible.
Penetrating the wall nearby, however, is feasible, and the recent tips
to use coax as the feedthrough medium sound really good.
Thanks for your reply, this antenna should be operational soon!

Thanks for your reply, Bob...

Unfortunately, the window is not feasible, but the coax approach
should work. MOunting to a small board or knockout might be a good
idea, so I could save the cut-out materials and be able to un-do the
hatchet work if that was ever necessary.

Thanks for your reply.

2491. Re: How do radio waves work?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-16 15:51:34 UTC
From: Buck <iam@this.site>
Message-ID: <fbp611tirb6jafka32eusnknn2qgubkvjb@4ax.com>
Source record: 81930

I have read the other responses, but let me take a stab at it.

I'll try to simplify this for you.

First of all, radio propagates by way of electro-magnetic fields. Since they are invisible, water is used to create a picture so you can get an idea of how they work, but they don't work exactly like water. Secondly, electrons are used to create the wave, but they aren't the waves.

You have seen how magnets attract and repel. You have seen an electro-magnet that attracts iron when it is energized and ignores it when turned off. Also, you have seen in a generator how a magnet passes nearby a coil of wire without actually touching it. Keep these in mind for now.

A transmitter causes electrons to move around in a particular fashion so they can convert information into radio energy, or an electro-magnetic wave. The circuitry manipulates and filters the energy so it has exactly the effect necessary to transmit on some desired frequency. The electrons are then sent through a transmission line to an antenna. The movement of the electrons in the antenna is like the electro-magnet producing an electro-magnetic wave. This electro-magnetic wave is then propagated into the atmosphere where it is effected by the conditions of the earth, the weather and the ionosphere. This is how the waves are created.

On the other side, the receiver is designed to convert those electro-magnetic waves into the electronic movement required to interpret or understand the information transmitted. Just like the electric generator, the magnetic field (waves) striking the antenna move electrons which are sent to the receiver, manipulated filtered and amplified and eventually converted back to a form in which the original information can be understood.

As far as the waves cancelling each other out, I have been told throughout my life that speakers need to be wired in a common manor, i.e. positive and negative appropriately, so they don't 'cancel each other out.' You may even have a speaker and/or stereo where the wire locations are color coded. I have NEVER heard one sound cancel another. It just doesn't happen. However, in radio, if you can get a perfect match on the phase of a signal, it can null itself out. However, that happening accidentally in the atmosphere is such a small possibility that you don't need to worry about it.

I hope this helps. If nothing else, maybe it can generate a thread of thinking in which you have new questions that lead you to the answer you can best understand.

Take care for now.

Dan,
Have a window fairly close to your transmitter/tuner? Replace
the glass with plexiglass, or drill a couple of holes in the glass,
or make a 'spacer' to fit in the window opening.
How about through the eaves, to attic, through ceiling?
'Doc

I have been thinking about that same thing. I hunt counties and therefore talk to lots of mobiles. Many times I talk to the same mobile in different locations. There are times I am received 59 and hear 22. Other times I hear 59 and get a 22. Since there are many mobiles throughout the country, I think I get a better picture of what propagation looks like than I would if I were just making random contacts. I live in the southeast and use a dipole, so for the most part, communications are in the same direction.

Here is my theory, as unsound as it may be. Think of a station with 100 watts using a TV dish style antenna talking to a person using just a dipole with 100 watts. The dipole user will hear a much stronger signal. However, on HF, we don't use dishes. Or maybe we do...

We know the ionosphere affects propagation. It is assumed that signals take the same path and therefore should have the same strength, but I don't think so. If the ionosphere is dense (relative to my frequency) behind and over my station, I may be using it as a 'dish' reflector. However, at your location, you may have a porous ionosphere so rather than your signal being reflected, it is being absorbed. The result is that I have an ERP of 200 watts and you reply to me with an ERP of 20.

This is just my theory I have in my mind and it may be that it is more full of holes than the ionosphere I put over your station in the example.

But, for what it's worth....

No, sorry, that is not what I had in mind and should have cleared that up right at the outset.

I never use coax connectors in this situation, although I suppose you could. I simply connect balanced line to the innter conductors of the coax's on each side of the balanced coax segment. If you want a quick disconnect, I use a pair of the General Radio type Banana plugs just inside the shack. They are convenient for several reasons.
1) they seem to be able to stand the power level.

2) the spacing on the wire connectors is exactly right for 450 ohm window line, and

3)they are hermaphroditic - i.e., they plug into one another either way.

We wouldn't want to disconnect the bamboo. That's the only effective antenna between it and the Ringo Ranger II.

Seriously, the Ringo Ranger II was my first anteena back in 1990 and I didn't know how poorly it performed until I changed to something else. To this day I've never had anything else perform that poorly. Everyone that I've talked to that has tried one has had the same expeerience. One guy tried two of them. He bought the first one used and thought that he had just gotten a defective one and ordered a brand new one with the same result.

You know, to be confused, you gave a pretty good review, BUT, if you'll reread our posts you'll see that we were not comparing the two antennas that Charlie was talking about. I was simply commenting on the Ringo Ranger II.

Reg, when I penned the thread beginnings I was trying to evoke
fresh thinking about the subject so as to challenge ideas that are spread by
plagurism in a similar way that the ballon is shown to demonstrate how
directivity /gain occurs.
Ham radio operators are lead to believe that the height above ground of
a beam's feed point determines the take off angle. It is true that it does
have an effect on the TOA, say 75 percent, when other actions are taken
to change the angle and 95 percent or so if no other actions are taken.
Thus if actions are taken to lower the TOA one can take advantage of
physical hops that were not available for a similar feed point height.
This is why I returned to the thread to dispute the statement that you
made regarding no amount of antenna waving can change the facts.
Regards from another indentured apporentice from the school of
Engineering and Navigation along side of the East India Docks
which was attended by many from the cable company further
down the river

My brother runs the Ringo Ranger and is very happy with it. It performs very well and increased his range tremendously. I was even looking into getting one for myself this summer. This is the first time that I had heard any bad reviews of the antenna. I will have to check into it some more.

thx Buck & Clark, and all, for your *attempts* ;).

I'm a little less confused and a little more confused. I think the most certainty I have is this: no, they don't have self-awareness cause if they did, they'd have seen my question and responded themselves, lol.

I'm glad nobody but Einstein2 understands EM, cuz that was my next question. I can picture something (electrons), but I can't picture nothing (waves of energy).

So let me see if i get this concept right.

First I create a carrier wave, then I modulate it with my message, then I send that from the antenna, which will converet it from electron "stuff" to an EM wave. So far so good? I don't quite understand how a carrier wave can both carry a message and itself not be a message, but whatever. (this part I can at least pretend to accept, even tho i don't understand the physics of it completely)

Next the wave travels through space in a way that totally dumb founds me, and is picked up by a receiving antenna, which does the whole thing backward. It's this part that really mucks things up (yes, that's the technical term for it) for me. I really don't see how there can be more than one thing occuping the same space (the whole "Back to the Future" phenomenon, lol) at the same time. Something is missing for me. I'm way more of a visual learner, so if anybody has pictures....SWEET. I can make the leap of faith because I know that color is frequency and a prism splits it up, but I don't understand how that works either. Back to Optiks for me ;).

thx again,
Bodi

Reg, G4FGQ wrote:
"It`s purely a matter of Spherical Geometry>"

Edmund A. Laport agrees with Reg in his book "Radio Antenna Engineering". On page 227 Ed writes:
"If, for example, the computed vertical beam angle for a one-hop circuit uses 6 degrees at an azimuth of 332 degrees and the horizon in this direction consisted of a mountain range with a height of 8 degrees, the performance of the circuit would be greatly compromised by the obstruction of the mountains. In such a case it might be better to work this circuit with two hops. Then a vertical beam angle of 20 degrees can be used instead, with adequate horizon clearance for the wave path. Or if the circuit required 6 degrees for a two-hop circuit 5400 kilometers long, with the same obstruction cited, one could change to a three-hop circuit which for the same layer height would permit the use of a beam at 14 degrees."

Best regards, Richard Harrison, KB5WZI

Used to be, exams weren't made "public". The FCC would give you a hint as to what "may" be asked, but not a list of questions with answers. I still have a copy of one of their "study guides". A single sheet front and back usually. Unless you knew electronics, you rarely passed. Then along came some wizard who thought the tests should be dumbed down. Now you have the books with all questions and answers. That sort of test taking does NOT prepare someone for the field. Any idiot can remember a bunch of answers after a couple hours of going through the book. It does NOT "teach" anything. I know some "hams" who don't even know what the hell a fuse is for. Imagine that!

It isn't the person's fault, their acquiring the license via the current system is just the way it is. But, that should not preclude them from picking up some books to "READ" about such things as antenna theory, building basics, etc. Without looking at some books, they'll be forever asking questions and not understanding. The Internet is a wonderful source of help, but there is only so much you can do. You need "reference" materials to get you going. READ BOOKS - THEN if you still have questions - ask..... The questions asked, should be the fillers - not the main content.

OR ..... you take advantage of diffraction abilities of physical parts
such as
mountain edges or other physical parts that can deflect the rays AFTER it
leaves
the FEED POINT which does NOT exclude an antenna array of which the feed
point
is part. The point of confusion emanates from.calculating hop distance on
the
basis of a :"standard:". TOA The "magic" of a stacked antenna exposes
the difference
:that occurs with a different TOA.
I suppose you could use Reg's program so that when the ideal conditions do
occur
maybe after several hours of waiting , when one can say that the upper
layers are now
exactly such or such a height and the assumption used in formulating the
program
are now correct. The fact is that ham radio is about formulating an array
that will
provide the hop distance required by the operator since that is something
he can change.
I am quite sure that LaPorte does NOT say that no amount of shaking an
antenna can

change the hop distance which is what TOA is all about and the subject of this thread.
Maybe we need another thread to clarify the question that Reg and yourself are
apparently addressing.

takeoff angle also plays a big part in this. One station may have a lower
angle and be making only 1 hop to the other station, while the other station
may have a higher angle and be hitting the first station via 2 hops --
resulting in some signal loss.

Hi Bodi,

That's because of relativity. Again we are speaking about inserting
an observer into the picture and gumming up the works (the proper
technical term).

>I really don't see how there can be
>more than one thing occuping the same space (the whole "Back to the
>Future" phenomenon, lol) at the same time.

This is part of Einstein's relativity, as described in Lorentz's
equations. It is found in the collapse of the space as you approach
the speed of light.

> I'm way more of a visual learner, so if anybody has
>pictures....SWEET.

Lorentzian/Einsteinian geometry predicts that at the speed of light
there is no third dimension in the direction of propagation. Hence
the sender and receiver do occupy the same space. This yields a
picture that is infinitely tall and wide (also a product of light
speed and the same prediction of geometry).

Now having said that, and offered a picture, I am sure that it means
nothing to you except as an example of metaphysical handwaving. Such
is mathematics when you divorce yourself from faith and its illusions.
On the other hand, blind faith in the illusions can bring some pretty
stupid conclusions on their own - just look at the comedy of
discussion about photons and electrons (well, maybe just skip this
advice and say you did look).

Buck wrote:
> The electrons are then sent through a transmission
> line to an antenna.

Since this is RF AC, I doubt that electrons actually make
it to the antenna from the source. Consider water molecules
carrying waves. The individual molecules don't move very
much but the wave does. Same for RF. The individual electrons
don't move very much but the RF wave does move at the speed
of light. For RF, the same electron is pumped back and forth
through the source. The energy impulse (wave energy) is what
moves.

Put your ear to a board and let someone hit the other end.
What you hear is sound energy that traveled the length of
the board but the molecules in the board hardly moved at all.

Or for a visual effect, consider balls hung on a string.
The end balls can transfer their energy to each other while
the center ball hardly moves at all.

> As far as the waves cancelling each other out, ...

Only coherent waves can cancel. Coherent waves usually
originate from a single source. Coherent waves can
originate from multiple sources only if the sources
are phase-locked or otherwise interlocked. Since our
ham radio RF sources are not phase-locked, they are
not coherent, and normally cannot cancel.

Doesn't reciprocity assume similar antennas and similar
power levels? Of course, someone running the legal power
limit into a YAGI is going to be received well by almost
everyone but someone replying with QRP into a short
vertical whip is going to be at a disadvantage. Changes
in polarization in the ionosphere can easily explain the
above if one station is horizontally polarized and QSOing
with mobiles.

Alex, I believe that the problem occuring here is that many are using words
like refraction, reflection
as being interchangeable. I see a mountainside when operating close to as a
reflector though
it may well be an absorber too. Anything, both behind or in front of a
driven element is a diffractor, thus its length alone
with respect to the driver does not determine whether it reflects or not.
If one solely focusses on the typical yagi
then it is easy to talk in general terms which are not applicable to other
arrays which leads to erroneous
descriptions. It is quite easy to design an array where there are many
elements behind the driven element and many
would be of lengths both shorter and longer than the driven element but
because they are closely coupled they can represent a single, longer element
as coupled elements introduces quanlities other than simple physical
length..

This is the area where photons are easier to understand than EM
waves (although an understanding of superposition of waves will
explain everything). Photons emitted from any number of sources
all arrive at your antenna at the same time. Those photons are
absorbed by the free electrons in your copper antenna. Your
receiver senses those electrons giving up their energies at
different frequencies, magnitudes, and phases.

Chicken, meet egg. :-) The electrons and water molecules are
the carriers of the waves and exist before and after the wave.
I know this implies something to carry the RF waves in free
space and there indeed seems to be something there. Empty
space is NOT empty. There is a structure of some kind in
empty space - maybe the extra dimensions implied by string
theory? Feel free to call it "aether". :-)

I run 9.5 Watts from a rare'ish grid square on 6m.
Almost everybody else is running 100W or more.
I get 5/9 reports from many, many S-3 to S-8 sigs. :-)
If I give _my_ rpt first, I nearly always get the identical or better
report from the other end.

Seriously, tho'. I've seen One-Way-Is-FAR-MORE-Favorable-Than-The-Other
propagation often -- on HF, and on 6M & 2M SSB.
I don't really believe there is _no such thing as_ one-way propagation.

And enter in the operator and their station

Alligator -- big mouth --- little ears

Elephant -- little mouth --- big ears

Excessive noise on one end of the circuit can be a problem also -- they simply don't hear you thru the noise on their end, you hear them fine. No contact.

>Doesn't reciprocity assume similar antennas and similar
>power levels?

Not both at once, I think.

The explanation I've seen of it is that if you have two radios having identical transmitter power levels, then each radio's receiver will "see" the same input voltage from its peer's signal even if the two stations have wildly different antenna types (pattern, gain, takeoff angle, polarization, etc.).

A change in one stations antenna which (e.g.) increases its gain in the direction of the other, will increase both stations' receiver-input voltage levels by the same amount... the changed station "hears" the other station better, and also "speaks" better to the other station by the same amount.

Naturally, the two stations may report different signal qualities during the contact, depending on the sensitivities of their receivers, on the local noise-floor level, on the presence of nearby in-band RFI which desenses the receiver, on the meter calibration, on the operator's hearing, on QSB which comes and goes at about the same rate as the conversation changes directions, and so forth.

Cecil
Sounds like cyclic flow changes between inductance and capacitance is
instantanious
leaving free electron that do not complete safe harbour to shove photons
towards
another antenna where it meets a similar cyclic flow between the inductance
and
capacitance which operates at the given frequency.
No, I have not read this anywhere but it is as good as any theories or
predictions
offered here since it appears to comply with Newton's Laws that have
been proven time and time again.
Regards
Art

Not a propagation problem I think :-)

Mother In Law's just don't come in full duplex , so she cant receive when
she is transmitting continuously...

Take any good 10 meter design -- and lengthen the elements OR
a 12 meter antenna and shorten the elements.
Standard theory here, found in any Radio Handbook (ARRL, RSGB, Bill Orr)
Library has copies or can get you one from their network.

Hi Doc...

There is an awning type window, however penetrating or replacing it is not feasible. In this particular part of the house, eaves & attic are not accessible and don't route to the hamshack.

However today I discovered two parallel runs of 1/2" Heliax which I installed in the late 70's and which have been abandoned and forgotten. These already exit up the hamshack wall, through the sole plate just above ground level, and route over the deck and underground to the location of a former tower. They can easily be cut off, and their center conductors used as the feed through...once cut I believe total length would be perhaps 6 to 10 feet; not ideal but would not require any new construction.

The planned open wire line will be 600 ohm type with about 5" spacing...need to figure a way to use banana plugs, gator clips or something like that to make the transition from wire to the center copper of the Heliaz...maybe solder some copper tubing over the Heliax center? A trip to the hardware store is in order.

Thanks and 73

Dan (K0DAN)

Here's my method to make a neat through the wall twin lead or OWL
feedthrough:
Materials: 3/4 inch or larger PVC pipe, 2 PVC end caps preferably with
flat ends,
2 lengths of 6-32 threaded brass rod (McMaster Carr) or True Value,
6-32 nuts and washers, RTV.
Cut the PVC pipe = the wall thickness + about 1 inch.
Drill and tap one end cap for the rods and drill 6-32 clearance holes
in the other cap. I used about 5/8 inch spacing.
Cut the rods about 2 or 3 in. longer than the pipe.
Drill a pilot hole from the inside wall through the outside with a long
masonry drill (use a stud finder to miss the studs). Use a 1 inch
spade style wood bit to bore a hole first through the inside wall and
then through the outside stucco. I was surprised at how well the wood
bit worked.
The rest of the story is pretty obvious. I'd use RTV rather than PVC
cement so that the assembly can later be pulled apart if necessary.

From: Tom Tretheway <tomt3@comcast.net>
Message-ID: <kOqdnZ2oRpyOhonfRVn-sw@comcast.com>
Source record: 81970

My new Cushcraft 2meter/70cm antenna is a very poor performer; so poor that something must be wrong. The only thing that doesn't check out are the "Reddi Match" elements. Should the outside tube of the "Reddi Match" elements have continuity with the center conductor of the coax, and thus the beam, and thus ground, like a folded dipole? Neather of mine do. There is no "physical" connection between the coax center conductor and the driven elements of the antenna.
All I can think of is that there are insulated elements inside the "Reddi Match" tubes which radiate to and from the driven elements. After checking everything, this is all that I can find odd.
Does anyone have experience with this model of Cushcraft, or a similar design, who can tell me if this is normal? Thank you in advance.

Tom

Message-ID: <11187vokd00ln44@corp.supernews.com>
Source record: 81971

Three possibilities:

1. One station is radiating more power than the other in the necessary direction. This means elevation as well as azimuth angle. You may both be applying 100 watts to an efficient antenna, but one might be radiating a lot more than the other in the necessary direction. If both sites have equal noise levels, the one radiating less power in the necessary direction will have the weaker signal at the other end. This is probably the most likely reason.

2. One station has a greater noise level. This might be because of actually greater noise reaching his QTH, or it might be because the other station's antenna has nulls in the directions where a substantial amount of noise is coming from.

3. Unreliable reporting. You should take all signal reports with a very big grain of salt. Different people have very different criteria for what constitutes an S9, or even R5, signal.

All these can lead to dramatically different reports at the two ends of the path, with no need for one-way propagation or violation of the reciprocity principle.

That's a really nice approach. I just discovered a pair of 1/2" Heliax feedlines already thru my wall...abandoned many years ago. If these fail to work due to impedance mismatch or other as yet unknown problems, I will try your brass rod in PVC approach...or one of the several coax thru the wall methods. So many answers, so little time!

>C>with mobiles.

And, Cecil, would this not be true if both were of the same
polarization as well? If the polarization changes, it changes from
horizontal and would be vertical at the recipient's QTH.

Just a thought.

2540. HF Direction Finding

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-17 08:02:26 UTC
From: Buck <iam@this.site>
Message-ID: <jgj8115010fbt155obg1uvoogkpbqqlo5j@4ax.com>
Source record: 81879

In WWII the allies were able to pinpoint the locations of German HF transmissions very accurately. They were able to pinpoint the locations of U-boats, etc. when they transmitted. (or so I have been led to believe).

What methods did they use to do this? Is it something duplicatable with Radio Amateurs in general or does it require some special type equipment?

I hear lots of amateurs describing interference and other problems on HF, but no one seems to be triangulating the offending stations. I am guessing that the real secret was in their communications with the 'spotters' to triangulate the positions.

Any suggestions?

Thanks

Triangulating and so on, can and does work. You're talking a difference between "war" and the need to know - vs - finding an offending station - to shut it down, etc. The FCC isn't as involved as many would like to think. They can't keep up with it. For others to do so, would be nothing short of vigilante-ism. It's not worth being jailed or shot - trying to shut down an offending station. Not to mention, most signals heard over hundreds or thousands of miles away. Who really cares? Would you be willing to travel the 1000 miles to put a stop to it? Probably not. Most new people can't change a fuse - let alone triangulate. They're lucky they recall what a resistor or capacitor is or does or even looks like once they put the book down.

I wasn't proposing that they 'shut them down' but to triangulate them.
I don't know how accurate the locations were during the war, but I
hear they were pretty accurate.

I think you agreed with my assumption that, basically, it is a matter
of amateurs not being coordinated, or more accurately from you, not in
the right location.

Sometimes the offending station is nothing more than a stuck keyer,
but sometimes it is intentional interference.

As for the competency, I hate to admit it, but sometimes what I see
leads me to believe my IQ must be about 250. That isn't to offend
those with high IQ's as those who have a real-life 200 IQ must be the
equivalent of about 600 now.

Oh well, off the soapbox.

I wonder if there would be any interest in long-range fox hunts (not
the QRP version.) :)

Source record: 81885

Looking at the instruction sheet on the Cushcraft website (since I wasn't familiar with this antenna), there is indeed no direct connection from the coax center conductor to the driven elements. This is a gamma matching network. The center coax conductor is connected to the inner tube of the "reddi-match" piece. It has a plastic insulator around it and slips inside the outer tube. This forms a capacitor. The RF "jumps the gap" from inner to outer conductor and then travels to the driven element via the small shorting strap connected between the reddi-match outer conductor and the driven element.

The places I would start looking for trouble is to measure the distances on the reddi-matches to match the instruction manual. Have you checked SWR with a meter? You also might check for continuity (and lack of short circuits) between inner and outer conductors of the coax "combiner" that attaches to each of the reddi-matches and allows a single feedline up to the antenna.

You were careful not to get any of that silicone grease (insulator!) into the center pin of the coax connector that is attached to each reddi-match assembly, right?

This is the same type of setup on my A147 2M yagi from Cushcraft and mine works fine.

2549. Icom AH-4 mobile users: radiating element?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-17 13:24:02 UTC
From: k5dh@raytheon.com
Message-ID: <SV0Rd.1$Or6.0@dfw-service2.ext.ray.com>
Source record: 81888
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

Icom AH-4 mobile users:

I recently installed an AH-4 antenna tuner in my mobile station, connected to my IC-706Mk2G. I'm using a 9 foot stainless steel CB whip as my radiating element, fed by about 2 feet of wire from the tuner to the base of the whip. What kind of radiating element are you using, and what kind of success do you have with it on 40m and 75m? I also have an Outbacker Perth antenna that I've used for many years, but I got tired of being unable to jump from band to band easily. I've thought about using the Outbacker with the AH-4, and just omitting the Wander Lead and matching transformer connection (in other words, use the Outbacker in its "raw" 75m state). I'm a bit concerned that the AH-4 won't handle this on 40m because the AH-4 manual says to avoid odd multiples of 1/2 wave, and that would be the case using the 75m antenna on 40m.

Let's hear your thoughts and experiences!

73,
Dean K5DH

I don't really see what your concept should be... Is it a troll or just for 11m band purpose?

You should better get a good antenna handbook to begin with.

Being one of the new nocode techs, I have no illusions re my overall radio technical competency. I have one slight advantage over my newbie brethren though. Having been a Jr. High shop teacher (woodwork, metalwork, drafting, and electricity) I at least have some idea where to look for info that will allow me to identify basic electronic components. Perhaps with license upgrades I'll widen my knowledge and competency base, but for now antenna building is my main DIY interest and such expertise is not yet required. Your comments on IQs is interesting. Many businesses, after laying off older workers for years, seem to be actively seeking elders again. Perhaps they've decided that it's desirable to have at least some employees that can both read and make change without a pocket calculator.(G)

A whip is down 6dB+ on 40m and down 12dB+ on 75m from a screwdriver. I guarantee
you will not be satisfied with it.

Very bad idea. Using an Outbacker Perth (wired for 75m) will result in very
large losses because of self-resonance.

Buck wrote:
"What methods did they use to do this?"

Terman says on page 1046 of his 1955 "Electronic and Radio Engineering::
"The fact that radio waves propagate away from the transmitter alomg a great-circle route makes radio direction finding a useful navigational aid."

Ships and aircraft have been equipped with shielded loop antennas for direction finding. At frequencies below 500 KHz,bearings can be read within 1%.

Ionospheric reflection so scrambles polarizations at higher frequencies, that loop bearings have higher errors.

An Adcock beam antenna can be made to ignore horizontally polarized waves from a certain direction and respond to only the vertically polarized waves. It suffers from very low signal pickup as compared with a loop, but gives accurate bearings at high frequencies over a distance of 100 miles where a loop would be useless.

In WW-2, aircraft and ships were often equipped with radios such as the Bendix RA-1B multiband receiver and a loop antenna, or the navy `s AN//ARC-5 equipment for direction finding.

Hi.
I recently completed just what you are planning to do. I got 2 NOS feed throughs last year on Ebay. They each consisted of a threaded rod with nuts and washers, two cone shaped insulators and more than enough ceramic cylinders, for the rod, to pass through my wall. I had to cut new cork gaskets to go under the insulators. The old ones just fell apart.

I had to construct a similar feed through for the connection to the ground just outside my shack. Here I used a threaded rod, two 1/4 in. plastic disks, and a plastic tube cut to length for the wall feed through.

If you are anywhere near a plastic supplier, such at TAP plastic, they will have all the stuff you need.

Good luck.

I was using a similar setup as yours. IC706MKII and the AH-4 tuner on a 9ft whip. I went back to my Webster Bandspanner and got consistently better results. While it was convenient when changing bands, it does little good if you cannot make the contact.

This setup might be good at the peak of a solar cycle when you can make the communications trip with lower power, but in average or below average conditions I think you are losing too much using the tuner and a whip.

Buck, N4PGW wrote:
"Is it something duplicable with Radio Amateurs in general or does it require some special type of equipment?"

Much British success in WW-2 in eavesdropping on German transmissions had as much to do with information processing as it had to do with its interception.

Germans used an "Enigma Machine" which was easily reset for a new code. They often changed the code and it was quite complicated. Germans used the machines to encode and decode their confidential messages. Early in the war, an Enigma Machine was captured. British code experts worked long, hard, and smartly to determine how the machine worked and broke its codes. Afterwards, the British were silent parties on the German`s war partyline. The British sometimes feigned ignorance so as not announce their access to Germany`s most secret information. It was a big factor in victory.

Stationary direction finding can take the directional antenna arrays used for transmitting and use them for receiving insteaad. Reciprocity means that the reception pattern is identical to the transmitting pattern. I have no idea what the British did in their enemy reception stations in WW-2. For HF, they could have used Yagi-Uda`s on rotators and indicators. They also could have used crossed loops or Adcocks, feeding a goniometer and not rotated the antenna. Terman shows how this is done on page 1051 of his 1955 edition.

During the "Cold War", when I worked in HF broadcasting, Radio Free Europe diligently monitored, recorded, and processed broadcasts from behinnd the "Iron Curtain". All the Communist news and commentary that was fit to broadcast from their point of view. To pick the desired transmissions from among the babble, some RFE receiving stations had the appearance of medium-wave multi-tower broadcast stations. Towers were tuned and phased to null interference and to grab the desired transmission. Other stations used sizeable loops. Some had air for a core and some had huge ferrite cores. Whatever proved best was used in any case..

Hams can surely use directional antenna systems.

Best regards, Richard Harrison, KB5WZI

I have run a similar set up with the SGC - the 2 foot bit in the car is a
serious
bad point, to the extent that SGC actually make a "bracket" that enables the
box to be clamped to the outside of the car and the whip is mounted on part of
this bracket,
right up very close to the output terminal - the aerial on these boxes starts
and is very "active" at the output terminal.

You HAVE to understand and appreciate that to make them work at all, if not
particularly spectacularly - they are primarily a "convenience box" over a
"performance box", so do have their place, but are quite a compromise.

Nick

Correct.

U-boats used HF for reporting back to base in Lorrient, but MF for talk among themselves in the Wolfpack. It was this that was DFed by the shipborne CRT DF.

Hi Dan and you make a valid point about feedline loss. I am feeding M2 HO LOOP with 65 ft of 9914F low loss coax which incidentally enough is a "direct bury" coax. I use a 35 ft run of 9914F for my Ringo Ranger II. I have a 50 ft run of the same 9914F direct buried feeding my Hustler 5-BTV vertical. At HF frequencies especially with 9914F there is virtually no loss at 50ft.

Link for 9914F coax, jumpers and assemblies and coax loss tables. The 9914F is within .1 db of 9913 loss figures but is more flexible and can be buried directly into mother earth....
1. http://www.radio-ware.com

TY for making a good observation but in my case your "preaching to the choir". Hi Hi

Hi Bill,

Another example of why BU is not MIT.

The geometries are wholly out of order with electrical resonance. The "antenna" is an opportunistic description, unrelated to its actual dimensions and operation. Calling the oscillations nanomechanical is fine, but it remains mechanical (phonons not electrons).

However calling it nano anything when the size is 1ï¿½M+ across (and tens of that in length) is a strain on the nomenclature. In other words, a technology trying to be hip - or putting old wine in new bottles.

How this "Holds Promise For Telecommunications" is another strain when optical coupling easily eclipses this vague puffery.

As for the claim of fastest moving nanostructure yet created begs the observation that these folks don't really have a very deep view of what is going on in the nanotech field. Going on to tie themselves into "quantum computing" misses the mark so widely (and wildly) is another clue of marketing being scattered in search of funding.

Hi Butch:
Sorry I don't have any information the Eagle log periodic. But I would think that anything less than 6 elements would not be of much use on HF. Unless it covered maybe only 20 to 15M or something. I have the 6 element version of the Tennadyne Log and I'm very happy with it. Not too big and works very will for me.

Brings back scenes from old WWII movies where the Germans were closing in on an Allied spy, with a suitcase radio set, sending from an upstairs flat, in the dark of night. Vans crawling along with loop antennas on the roof, and guys inside with comm gear and headphones telling the driver where to go, etc.

Wonder if loop antennas were what they really used, and how good they were? The spies generally used cw. How do you get a fix on the short dots and dashes?

Small loops are still used and seem to be very effective for DF. I think that the ARRL antenna book provides information in this direction. One system I saw used a short ferrite dipole array.

In most cases, DF sets displayed their goniometer outputs on a CRT or as signal strength on a meter. In this case, the dots and dashes melded into a continous output because of the persistence of the CRT or the AGC delay of the receiver.

The first DF equipment I used on the ships was WWII vintage and very effective on any type of signal.

As a point of reference, the radiation patterns of sidemounted FM broadcast transmit arrays are affected by a non-resonant mounting structure (the tower) -- especially for vertical polarization. Measured patterns from the manufacturer's test ranges demonstrate this, as do the NEC-2 studies in several of the papers on http://rfry.org .

Source record: 81920

I'm wanting to build a receive VHF yagi covering the marine band, that is from 156.025 - 162.05 Mhz (6 Mhz frequency range).

I want a design that maximises gain.

I would have thought that what I need is a wide-band yagi, but that's all, not a very-wide band yagi.

Should I be using OWA design? Or what?

BTW, given the frequencies above, what is the yagi bandwith I'd require? I mean, should I be building a yagi described as having a 6Mhz bandwith?

TIA.

Message-ID: <qf3c1156ludc03i7o48c1lk9dhilil970m@4ax.com>
Source record: 81824

Intellgence agencies when they did HFDF used huge antenna arrays
called CDAAs (Circular Disposed Antenna Arrays). They were also known
as Wollenwebbers (presumably after an inventor). These arrays were
often very large, and sometimes were affectionally known as "elephant
cages." The diameter of these arrays could be as small as 50-60 feet
for a tactical unit to several hundred feet for large fixed sites in a
secure area. Each circle had many vertical elements.
They measured time difference of arrival by measuring the wavefront
timing on each antenna in the array as the wave passed through the
array. A computer then collated this information to calculate a
bearing. The readouts varied depending upon the era. Some were
digital, some were on an oscillicsope. I'm not quite sure how the
really early ones worked (before my time). The results of several
stations were then combined to get a "fix." Contrary to popular
belief, their accuracy had significant error factors so despite many
requests from military commanders who wanted to drop ordinance on a
target, you really couldn't do that based solely on HFDF. HFDF was
really originally intended for open ocean surveillance against things
like German subs in both WW I and WW II.
You could get a rough idea where a signal was coming from and then
you would have to sent a destroyer or aircraft to actually locate the
sub. There are other types of HFDF antennas as well, but none can
give pin point accuracy unless you are mobile and close in as in
transmitter hunts. As long at there was energy, you could get a
bearing be it a sustained carrier or a single dit. You would have to
rely on other externals (callsigns, radio finger printing etc) to
figure out who was sending a given signal.

Futher: Some time ago I did download 4nec2, and obtained some yagi models. I would have thought that all I have to do is scale one of these models and then make corrections for the physical construction.

I managed to catogorise the models thus:

DJ6BV
OWA
SM5BSZ
VK3AAU
W6SA
Wideband Yagi (eg such 220-4eleYagi.nec) Not sue what this design is.
Wideband yagi W4NRL
Yagi (eg 220-3eleYagi.nec) Not sure what this design is.

One of these designs got to be wideband and maximised for gain I suppose.

But geing closer to the driven element(s), probably even non-resonant antenna elements may have more affect on the net antenna pattern than that produced by a supporting tower further away.

They were simple and with a good null. Only with arrays will you get a
better null.

Just swing the loop for minimum signal.

I don't think there was a swinging goniometer with the CRT DF set. The
output of the two loop aerials fed the X and Y plates respectively so
that the trace appeared at the right angle and the bearing was read from
the screen.

Sorry for vagueness. Yes, they used the lower frequencies for short
ranges, probably because the LF didn't travel far. (But far enough for
the RN)

There were a number of different types of DF sets. Some, as you
point out had x and y
plates connected to the loops, another had a mechanically rotating gonio.
We had one for radar detection which used horns with crystal detectors in
it which went to x and y plates (through amps). The HFDF used loops feeding
a mechanically rotating gonio with output to a crt.

2590. Ladder Line and wind

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-18 17:11:05 UTC
From: Jim Miller <jim@removethisjtmiller.com>
Message-ID: <T7adnfKO6L8uvIvfRVn-pA@comcast.com>
Source record: 81829

I'm putting up a doublet centerfed by 450 ohm ladderline. It will be about 50ft away from the house to the feedpoint of the antenna. We live on top of a hill and winds here are often gusting to 60mph. The typical direction of the wind is perpendicular to the ladderline and I'm concerned about it whipping itself to death.

The ladder grabber at center of the doublet will be supported by a line running from the house to a tree so I'm considering attaching the ladderline to the support line leading to the house to minimize the whipping. The ladderline has to come this way anyway. This support line will be perpendicular to the axis of the antenna.

I briefly thought about threading the house line through the ladder windows but that seemed likely to spoil the impedence especially if wet.

Any concerns or recommendations?

tnx

I'm putting up a centerfed doublet fed by ladderline and an antenna tuner in the backyard and have two trees to support it which are about 112ft apart.

I could put up an 88 foot doublet between them easily. However would it be better to put up a full 100 footer (allowing for endline support) since I have to tune it anyway or is 88 foot a better choice?

It will be used for hambands as well as swl.

Using EZNEC, one can observe that the current in a
closer non-resonant passive antenna element can be
pretty low while the current in a grounded tower
further away can be pretty high.

All about DF, sense antennas, nulls, etc
http://www.avweb.com/news/avionics/183233-1.html

Side note -- A WWII B-24 bomber (Lady Be Good) ran out of fuel because they were not sure of the DF readings --that is -- if they were going toward or away from the home station. Crashed in the Libyan desert -- all of the crew perished after walking as far as 85 miles in the desert.

See URL:
http://www.qmfound.com/lady_be_good_b-24_bomber_recovery.htm

On our Navy planes in the 50's we had two ARN-6 - ADF (Direction Finders), 100-1750 KHz
In conjunction with Loran -- we usually knew where we were. (;-)

But also the Navigator would take periodic sextant readings (weather permitting) thru a bubble on top of the aircraft

No GPS in those days.(;-(

On one of the squadrons flights -- a circuit breaker blew and refused to be reset -- avionics were off -- the crew flew dead reckoning most of the rest of the flight.

Cecil, W5DXP wrote:
"Passive non-resonant elements have very little effect."

True in a parasitic array such as a Yagi.

In some antenna arrays all the elements are fed by a transmission line. Directional arrays are also made by using elements which are not connected to a transmission line. These disconnected elements have current induced into them by the driven element and are called parasitic elements.

The effect of a parasitic element depends on the magnitude and phase of the current flowing in it. To get substantial current, the element must be near the driven element or other element carrying large current, and it must be almost resonant. A non-resonant element has a large reactance limiting its current flow and effectiveness.

A resonant length for a conductor in space is 1/2-wavelength.

A resonant length for a grounded conductor is 1/4-wavelength.

The 3-element Yagi is a common parasitic antenna. It has a driven element, a reflector element, and a director element. The length of all three elements is nearly 1/2-wavelength in most cases. To get large currents, near-resonance is essential.

The trick is to get the radiation from all elements to reinforce in the desired direction and cancel in other directions.

Phase of current in the reflector is often delayed by making it slightly longer than a 1/2-wavelength. Phase of current in the director is often slightly advanced by making it slightly shorter than a 1/2-wavelength.

Spacing between elements is close to get a large excitation of the parasitic elements. This makes a compact antenna. Close spacing means mutual impedance (coupling) between the elements, and this affects the drivepoint impedance. Close spacing increases directive gain but lowers the array`s radiation resistance. See Terman`s Fig 23-36 on page 904 of his 1955 "Electronic and Radio Engineering".

Large non-resonant reflectors are also used. Backward radiation can be eliminated with a plane conducting sheet. It`s impenetrable and must reflect. The earth often acts as such a reflector. The parasitic 1/2-wave reflector is a "degenerated" (Kraus` word) case of the plane reflector. I recall that either Kraus or Terman suggested that the best way to handle non-resonant reflectors was on an image basis.

Best regards, Richard Harrison, KB5WZI

>manufacturer's test ranges demonstrate this, as do the NEC-2 studies in
>several of the papers on http://rfry.org .

Check... that's just the sort of situation I was thinking of.

The effect on the pattern isn't all that strong, though... only a few
dB. As one example, the old ARRL VHF book gives the plans for a
four-bay stacked dipole antenna system. With the dipoles placed on
four sides of the mast, the antenna system has a gain of about 6 dB
(they don't say dBi or dBd but I assume it must be the latter). With
all four dipoles on the same side of the mast, the pattern is said to
be a cardioid of about 9 dB gain.

They don't say how deep the back-side null is. The cardioid pattern
might have a high enough F/B ratio to help with the original poster's
situation (mountain-side reflection), or he might need to use a tuned
reflector of the 5%-longer-than-resonant variety to get a more
directional pattern.

Hi Jim,

The whipping action is due to vortex shedding - an imbalance of wind pressure on each side which is oscillatory in nature. To cure it, the simple resolution is to twist the line so that the face of the line rotates every 12 to 18 inches.

Hi Richard,

If you do this literally so (even to element thickness). Some slop is
tolerable in going from one VHF frequency to another, but from HF to
VHF you need to scale closely.

>One of these designs got to be wideband and maximised for gain I suppose.

4nec2 should resolve this - it is its purpose after all.

Reg,

The alleged conditions you describe are not found in the people who do this, and if it were present would still have zero bearing on the cause of these lunatic suicides. Fractional existence and/or slavery may be found all over the globe and was rarely ever a cause of such insanity. Only the influence of Islam allows such departure from humanity and any hope of a better life here on earth. Islam executes this insane belief not only on others, but on themselves. A combination of education and eradication (genocide) may be applied as needed to calm this insanity. Londoners have their own form of insanity, that of banning guns from law abiding citizens whilst encouraging Muslim Mosques to add to the near 40% Muslim population who preach for the destruction of the West from inside the London city gates.

My ladderline seems to do fine on windy days, and I did nothing
special to limit movement. You might bring it directly to your shack,
and if the wind bothers it, just twist it as someone else has
suggested.

On your other question, about doublet length, if you make it 102 feet,
it'll be G5RV-length, and there are plenty of articles on how those
perform on the various bands.

On the receive side, I don't think you need to worry too much. If you
create a yagi for the center frequency, you may find very little
difference on the ends of the spectrum you want to monitor.

The wider spaced the elements, the narrower the bandwidth. I don't
know how much, if any, you will notice a difference at the band edges
with that beam.

Good luck

Jer,

No insulator is required. Either kevlar or cotton line (even when wet) have about the same resistance as a wet or dry insulator, which is next to nothing. Insulators or the lack thereof do not affect transmitting (<1kw) and they most certainly do not affect receiving. About the only thing the special antenna-to-rope/line insulators do provide, is a form or strain relief due to the wide-radius of turn around the insulator. This means when the line holding the antenna breaks, it will probably break at your rope knot, not at the soft-curve around the insulator. Big deal, huh. To conceal a wire antenna, don't bother with insulators of any kind.

73,

Jack

All the models I have are VHF ones.

Actually the bandwidth of the marine band, in terms of percentage is
6/159.025 = 3.78%. So, any beam ought to have a useble range of 3.78% at the
operating frequency. (I guess though that for any particular design it's
bandwith could be a producy of your personal SWR tolerance). I'm not even
sure if a yagi I need is just a regular one or a wideband type.

Anyway, I guess in truth, of those designs I mentioned, quite a few would be
satifactory. ie:

DJ6BV
OWA
SM5BSZ
VK3AAU
W6SA
Wideband Yagi (eg such 220-4eleYagi.nec) Not sue what this design is.
Wideband yagi W4NRL
Yagi (eg 220-3eleYagi.nec) Not sure what this design is.

I think perhaps I could probably go for any, (not sure about that) but folks
seem to rave about DL6BV designs and I think they may have a the requied
bandwith, but I'm guessing here, not being much of an antenna buff.

Hi Cecil,

I have one too - and I am sure it does make an excellent mobile antenna
system with 13 feet on its output.

I use mine for "hotel room use" mainly, or any quick lash up in available
space.
I am constantly amazed by the results I get and wouldn't part with it.

On the car I use a resonant whip about 3 feet long on the gutter for 40M and
equally that works well....

For a permanent fixed sytem though its an expensive convenience over other
systems
based on e.g. wire dipoles.

It is a great box though !

Nick

Richard

I dont have any *one* Yagi design to recommend for your 160 MHz
application. But, I sure do like playing with Yagis. I have a few
questions about your design plan for this antenna.
The gain from a 3 or 4 element Yagi isnt more than you could get from a
omniazimuth colinear array, and I suppose you will prefer vertical
polarizathion.

Jerry

Jack, who are the lunatics? To have faith in your religeon or beliefs is not insane,
We have christians who have faith in religeon and beliefs. In war many have given up their lives
to save others and we have in fact declared war against a religeon.,
Regarding Londoners having their own form of sanity, go to Hyde Park corner on a sunday
and hear the free speech that is the right of all even if you may disagree with it..
Regarding the gates of London of which there are eight which surround one square mile
if you say that 40,000 dwell inside those gates then many must be squatters inside the palace walls.
Reg is speaking as a European where the main threat of war in the world is seen to come from the Middle East
with the help of the U.S. Why else would we deliver 50 of our most sophisticated deep concrete bunker
smart bombs? Surely not for destruction of tents and shacks but more probably to penetrate heavily concrete
nuclear energy stations like their own. I believe Reg is sincere and correct in asking the USA from the other side of the pond regarding what we do in the Middle East. WHY?
As far as banning guns, I do believe they ban hand grenades and a plethoria of other weapons that can only
be used to kill people. It is a democratic country and it is the peoples will, why are you concerned about it?.
If there are many close by to you who have the same beliefs as you regarding genocide you may have to coinsider
whether you want to kill or be considered to be one endangered by the killing. Your religion may well be different
to your immediate population

Richard, if you live in an area plagued by pager-interference to the marine-band, you may notice real improvement by a narrow-band yagi. I used to use a wide-band yagi for marine but abandoned it due to its impracticality in trying to cover 300 degrees of traffic from my station location. Even so, with its large front to back separation and fairly narrow directional gain, it did help reduce pager-interference.

Hello Art,

I've been to London, and I never heard lunatics advocating the violent destruction of all things related to the "West" as we know it. But then I stayed out of Mosques, too. The reference to the city gates was anecdotal only. The 40% was a figure given to me by a London couple I met last week, when I quoted 30% muslim population living in London, apparently an old figure. This particular British couple I met happen to approve of both President George Bush and our mutual (countries) efforts to eradicate radical muslim actors. They also have a soldier-son in Kuwait so perhaps they are privy to information we are not.

We have not declared war on the nation of islam, but we should, because they have long ago declared war on the west and all of our tenets of free religion, free economies and forms of self-government.

Wise up and stop defending that which is focused on your own destruction. It has nothing to do with free speech. It has everything to do with survival. I don't mince words, and genocide is exactly what it will take to survive the onslaught of islam. Education may prevent it from reaching the level of insanity it presently enjoys. It enjoys this status largely due to the tolerance of fools who think their elected legislators represent them. Perhaps Reg remembers when Chamberlain lied to his countrymen, waiving the "peace is at hand" (paraphrased, Art) toilet paper that Nazi Germany gave him. Saying that Islam is a "peaceful religion" is the same rubbish.

Regards,
Jack

Interestingly, aircraft used small loop type antennas for MF/HF DF in the 40s and 50s. Just turn loop for a null, and (maybe) use an omni sense antenna. Two spaced reception stations give a reasonable fix for a ground system.

Actually maybe I'm barking up the wrong tree. Maybe a co-linear is the way to go. I live about 70 miles from the sea, but maybe a good co-linear is as good as a 4 element yagi. I can receive a marine station from my location, and there is some marine traffic originating from canal boats about 30 miles away.

The Trakbox will aim your satellite antennas automatically. Controls your AZ-EL rotators. Just select one of the sats in it's user defined database, and it will track that sat. Check it out on ebay. Auction ends Feb. 28th, 2005.

Richard

Since you have complete control of the performance specifications for
this is an antenna you can build almost any Yagi and try it. A 6 db
colinear array could be difficult by comparison
70 miles is quite a long didtance for that kind of communication. I hope
you are located well above sea level.

Jerry

Adcock arrays http://www.airwaysmuseum.com/HF%20CR%20DF%201.htm
http://members.aol.com/BmgEngInc/Adcock.html
worked quite well, but they require precision in construction, as well as
the site.
For VHF/UHF, there are all sorts of things available :)
N0MKJ and I used to hunt with the "fox-copter", featured in the 3/94 73
magazine.

Here's some references in 73 magazine:
http://www.pejla.se/ardf_litteratur.htm

And a bunch of links to play with:
http://www.dxzone.com/catalog/Operating_Modes/Radio_Direction_Finding/

Does anyone have any knowledge regarding RF exposure issues from a small resonant loop antenna at HF frequencies? In particular, I am concerned about the very large magnetic near-field.

Thanks,

JJ

Wullenweber: German for wool weaver. Germans had several in WW2, none existed elsewhere. Sites were stripped and
burned and the big iron goniometers buried during the closing days of the war. Took quite a bit of effort by ONR and
OSS to retrieve enough material to reconstruct the concept. And a lot of work at U of Ill. and ITT/FTR to make one
work. Beamformers, not TOA. That came a lot later.

The initial question was set in the WW2 time period, I believe.

Crazy George
the ATTGlobal.net extension is a SPAM trap. Use att dot biz instead.

Islam can be a beautiful, satisfying religion, or it can not. Like some of the gutter Christian sects infesting America there are people who profess a belief in God who would use that belief as an excuse for killing innocent people. People who preach genocide are low, anti-social, dangerous, and a danger to society and should be locked up to keep them from doing harm.

I guess I should clarify that the 2 foot piece of lead
wire is all outside the vehicle except for 4 inches.

I overheard a station the other day saying that he was
using an AH-4 to load a 17m HamStick on all bands from
75m through 10m. I was thinking of doing the same but
using a 30m HamStick (not resonant on any ham band that
allows SSB operation). Anyone tried this?

Aunwin, it is indeed reassuring to hear from a USA citizen, a voter, who can distinguish between the weapons of mass-destruction possessed and EXTREMELY EXTENSIVLY USED by the USA during the last 60 years on the towns, cities, rice fields and jungles of innumerable countries of this small Earth of ours, as distinct from civilised Briitish Gun Laws and the mixed-up religious population proportions of this still-free country.

Some people need to be reminded there has NOT YET been a single so-called terrorist attack on the UK by anybody except, for many years, by the Irish Republican Army, which is but one of the many disruptive international organisations financed by the CIA and, via USA taxpayers, the USA government.

But, as the USA government quite openly states, all is being done in the very well-worth-while interests of USA citizens. Who can blame them? They are only ordinary human beings after all.

To them, including USA drug-addicted soldiers, their lives are considerably more important than the remaining five billions of humanity who are doing their best against Aids, Earth warming, chicken flue virus, earthquakes, floods, starvation by the tens of millions, and shortages of clean water.

Solution - bring the International Energy Corporations under control.

It must now be assumed I am on the master list of the CIA's Dirty Tricks Dept computer and liable to disappear from circulation at any time.

And, to return to topic, to keep yourself sane, get yourself a free program.

Source record: 81775

One night in 1944, there were a thousand Lancaster killing machines and other RAF bombers over Germany, complete with aircrews who well knew what they were about. It was a moonless and cloud-overcast night over the whole of Western Europe. Targets were civilian firestorm-raids on German towns and cities.

Navigation was via GEE equipment, a British hyperbolic, pulse-radar, VHF, 1942 invention which later, as the LF and VLF versions, was given the American name of LORAN (who copied it in the same size boxes.)

With GEE it was possible to accurately navigate several hundred miles from base and return safely even with fog over the airfield. Aircrews had become to depend on it and had neglected, forgotten how to use, other means of navigation such as dead-reckoning and the magnetic compass.

From shot-down and crashed aircraft the Germans had discovered the frequencies used by GEE receivers and fathomed-out how the equipment worked. But instead of using jammers immediately as they came out of the factories they waited until there was an appreciable quantity of them, waited until navigation conditions were difficult, no moon or stars, dispersed the jammers around Europe, waited until there were a 1000 bombers in the air, and then switched them all on simultaneously.

German radar-controlled anti-aircraft guns were always accurate. They were used in clear skies in daylight, sometimes in preference to optical instruments and range finders. Hundreds of bombers, lost, wandering about Europe were better than usual targets.

More than 100 heavy bombers failed to return to base. Some crash-landed, running out of fuel in Sweden, Poland, central Europe, northern Italy, France, even in north Africa. Others came down in the north sea. It was the geatest disaster in one night ever incurred by the RAF.

Although heavy losses and damage to aircraft was a normal event, the loss of more than 100 trained aircrews was a catastrophy. Incidentally, during the whole war 40,000 aircrew lives were lost due to enemy action and another 30,000 were lost due to flying accidents of one sort and another.

But, as usual, Uncle Sam helped us out. GI's left behind 70,000 unmarried mothers in the UK.

I just love statistics! ;o)

Reg.

I use banana plugs to disconnect the ladderline when it looks stormy.
Lately, I've found Radio Shake sells some pretty nice, heavy duty
banana plugs, better than what I've found at hard-core electronics
stores.

Not sure how well any lightning arrester would work, but the Wireman
sells a couple of arrestors for balanced line -- one, a contraption
with 2 spark plugs, the other, a device from I.C.E.

then Tom added:
>Religious fanatics of every stripe are dangerous, whether they be
Christian, Hindu, Moslem or anything else. So, too, are political
fanatics. The West has plenty of both.

Tom Donaly, KA6RUH

Well Tom, fortunately for you, there are rough men ready to fight in the middle of the night on the other side of the world, in order that you can sleep in your bed free from fear. As to your thinking that I should be locked up, I nonetheless defend your right to be a useless twit, unable to stand for anything, and able to make dribble about righteousness without a defining origin of those thoughts. Everything is o.k. with you, except things that suck. Someone should take care of that stuff for you, so you don't have to worry too much about it. Gotcha. Oh and Tom, we'll be watching for those zealous Christian sects infesting America, watching for the first sign of their *suicide bombings*. In the meantime, maybe you can point to some evidence of Christians doing that anywhere in the world, ever.

Jack

On DF antennas sense was always something to be taken with a grain of salt.
It was quite easy to have a reading 180 degrees out. We always had to consider
other factors about the targets such as where the coast was, or where the
last reported position of the target was.

I spent most of my time in the navy as an operator, then supervisor technician ('57 - '83) with shipborne electronic warfare. After commissioning I was Operations Officer at two Canadian stations who were part of the USN based Bullseye HFDF system (Wullenweber Antennae), and then as Operations Officer at CFS Alert, a small sigint/comint station at the northern tip of Ellesmere Island (300 miles north of Thule). Brrrr.

I went from pre-WW2 DF equipment (Canadian Navy was always a little slow in updating), to the latest state of the art -- or at least it was in 1983 when I left. It was a most interesting career. It still is, for the guys who are still in it.

You might find some good information and links on my Oldtimers Website listed below.

There was one shown in one of the earlier ARRL handbooks.

I second Bob's reference to Industrial Communication Engineers (ICE)
products. After a lot of study and customer reference-checking, I specified
some of their products and have been very satisfied.

While the products can be purchased direct from the factory, they do not
undercut their dealer, Array Solutions (a very reputable company and easy to
work with).

Your balanced-line arrestor is listed here:

http://www.arraysolutions.com/Products/ice/impulse1.html#2

Because coax or balanced-line surge protection devices are only a small part
of lightning protection, I invite you to take a look at a few pages I
assembled on the subject. Disconnecting everything before a storm arrives
requires diligence at all times during thunderstorm season, and often panic
when the diligence fails you (when a sneaky T-cell develops right on top of
you). There are easier, albeit expensive ways to sleep better.

Yes, returning to the subject of TOA the antenna I am working with has a
natural TOA of 10 degrees instead of 14 degrees with the feed point at 65
feet
(for 20 meters. tho it can also be used on other bands)
If the antenna is tipped up to angles beyond 15 degrees the TOA increases
until it goes straight up.Thus the antenna can choose the correct angle for
a particular QSO or hops even if the wind is not "waving the antenna
about"! Grin
At present I am searching for a way to DECREASE its natural TOA.by way
of a 2M antenna project and if succesful will dispatch it to the RSGB for
comment.

And your problem is?
Being of German descent with relatives in Germany, I feel that the
German people got what they deserved. Actions by the Luftwaffe were just
as horrific in London, Warsaw, Stalingrad and Antwerp to name a few.
The Luftwafe had similar devices to locate their targets in England with
the same results when their systems were captured by British Military
Intelligence (what an oxymoron).
BTW the Lancaster was one of the finest aircraft of it's type ever.

2646. Re: Icom AH-4 mobile users: radiating element?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-19 04:26:30 UTC
From: nm5k@wt.net
Message-ID: <1108787190.020216.229060@z14g2000cwz.googlegroups.com>
Source record: 81785
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

I overheard a station the other day saying that he was
using an AH-4 to load a 17m HamStick on all bands from
75m through 10m. I was thinking of doing the same but
using a 30m HamStick (not resonant on any ham band that
allows SSB operation). Anyone tried this? ....

It's pretty mediocre...It would be much better to actually tune
the hamstick to the different bands by changing the stinger
length.
But it would take a long stinger to tune 75m, with no loading
coil. A 10 meter hamstick can tune 20m by adding appx 2 ft
longer a stinger. A 20m stick can tune 40m by adding about 4-5
ft of stinger. I did that for a while, and it works much
better than you might think.
Myself, I always tune the antenna to resonance by using a hi-Q
loading coil. There is less coil losses, but also the current
distribution is much better, which raises the efficiency
quite a bit.
I just mounted my antenna on my #2 truck. It's even
higher than my other truck. I installed a ball mount on
the cab, about 6 inches below the roofline, on the pillar
between the back window, and my side window. The base of the
antenna is 64 inches off the ground. My antenna is 11 ft
total height, and is center loaded in the driving mode.
That puts my loading coil at about 124+ inches off the ground.
The stinger is 5 ft...Yep, it's tall, and I whack trees
o-plenty. But it works very well. I also have a 3 ft mast,
that I can add to the antenna, and have the coil 8 ft from
the base. The total height is about 19 ft....:) Naturally,
I don't drive with it that tall, but use it stationary...
That antenna compared to a tuner loaded whip?
Ain't none...:(I'd probably be 2-4 S units louder than you
on 75m to the average person...
A friend of mine wants to run a tuner loaded whip...I can't
talk him out of it...Oh well...I'll catch him some day after
he installs it, and do a side by side comparison with my
antenna. It's gonna be ugly the way I spank his heiney on
75m....:/ 40m too, to a slightly lesser extent...
BTW, I also have a shorter 10 ft antenna , with the coil at
about 2.5 ft off the base...It's my old antenna...But I'm
gonna use it on this truck for a "heavy tree" antenna when
I'm in town...With the coil lower, it will take trees better.
But I'll use the other anytime I'm on the road. This

is the highest I've mounted a mobile so far...I'm over the
legal limit of 13.6 a bit, being mine is about 16 ft tall
total..But it sways back, so when moving I can clear stuff
lower than that. A tuner loaded whip is ok on 20-10, but
even still, the hi-q coil antenna is still that much better.
On 20m, my antenna is like being at home...I don't use many
turns of coil on 20m...The efficiency is pretty high.

Unmitigated hypocrisy. The British have no business sticking their
noses in the air over our behavior in Iraq. An example: there have
been two men who have been responsible for

using poison gas against civilians in that country. One of them is
the infamous Saddam. The other is the great British war hero
"Bomber" Harris, who, like Adolph Hitler, believed you could win
wars simply by slaughtering innocent people.
Stick your nose in a history book, Reg, and you might be able
to cure yourself of the habit of making these asinine posts.

Hamsticks have a nasty characteristic. A 75m Hamstick is
self-resonant before it gets to 40m. A 40m Hamstick is
self-resonant (~9 MHz) before it gets to 30m. Self-resonance
is the frequency at which the inductive reactance equals the
stray capacitive reactance and results in heavy losses. I
don't know the self-resonant frequency for a 30m Hamstick
but I'll bet it's lower than 14 MHz.

Drooping has little effect on 80m but drooping 1/4WL on
each end can have major effects.

Many atrocities have been committed over the years in the name of Christ. That doesn't meant that Christianity is bad, but that there have been people willing to use it as an excuse for slaughter, as you do. Face it, Painter, when you advocate genocide, you're no better than the Islamic fanatics in Saudi Arabia calling for the annihilation of the infidels, or the racialist bigots of Nazi Germany screaming for the elimination of the Jews. Moreover, you should get something through your thick, Southern skull before you and people like you do something stupid: there are Islamic countries that possess nuclear capabilities. You're not going to be able to murder the people of those countries without getting something back in return. You need to calm down and quit watching those hick preachers on T.V. on Sunday. Maybe you should get out of your easy chair and go to a real Christian church and learn some real Christianity before you shoot off your mouth on this newsgroup and make a fool of yourself like Reg.

Tom, remember mustard gas used in the first world war?
Terrible stuff to use yet the largest stockpile in the world
of that terrible stuff is held in mid U.S., for what reason
I do not know, Do you?
Regarding Commander Harris, are you saying that he took a squadron
to Iraq and sprayed poison gas?
Art

Im tellin yah it workx and its so worth it

Turn $5.00 into $50,000...read this to find out how!!!
READING THIS COULD CHANGE YOUR LIFE!!!
I found this on a bulletin board like this one and decided to try it.
A little while back, I was browsing through a newsgroup, just like you are now, and came across an article similar to this that said you could make thousands of dollars within weeks with only an initial investment of $5.00! So I thought, "Yeah right, this must be a scam", but like most of us, I was curious, so I kept reading... I also did an internet search and found nothing but success stories.

Anyway, it said that you need to send $1.00 to each of the 5 names and address stated in the article. You then place your own name and address in the bottom of the list at ..5, and post the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So after thinking it over, and talking to a few people first, I thought about trying it. I figured "what have I got to lose except 5 stamps and $5.00, right?"

Then I invested the measly $5.00 (I use the word "measly" because $5 really is measly compared to the money I have made through the initial investment). Well GUESS WHAT!!... within 7 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in.
In my first week, I made about $25.00. By the end of the second week I had made a total of over $1,000.00! In the third week I had over $10,000.00 and it's still growing.

This is now my fourth week and I have made just over $42,000.00 and it's still coming in rapidly. It's certainly worth $5.00, and 5 stamps, I have spent more than that on the lottery!!
Let me tell you how this works and most importantly, why it works....
Also, make sure you print a copy of this article NOW, so you can get the information off of it as you need it.
I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy!

Suggestion:
Read this entire message carefully! (print it out or download it.)
Follow the simple directions and watch the money come in! It's easy.
It's legal. And, your investment is only $5.00 (Plus postage)

IMPORTANT:
This is not a rip-off; it is not indecent; it is not illegal; and it is

virtually no risk - it really works!!!! If all of the following instructions are adhered to, you will receive extraordinary dividends.
PLEASE NOTE:
Please follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days.
This program remains successful because of the honesty and integrity of the participants. Please continue it's success by carefully adhering to the instructions.
You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists.
Many large corporations are happy to pay big bucks for quality lists. However, the money made from the mailing lists is secondary to the income which is made from people like you and me asking to be included in that list.
Here are the 4 easy steps to success:

STEP 1:
Get 5 separate pieces of paper and write the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING LIST."
Now get 5 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper so the bill will not be seen through the envelope (to prevent thievery).
Next, place one paper in each of the 5 envelopes and seal them. You should now have 5 sealed envelopes, each with a piece of paper stating the phrase "PLEASE
PUT ME ON YOUR MAILING LIST.", your name and address, and a $1.00 bill.
What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL!
You are requesting a legitimate service and you are paying for it!
Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal!
Mail the 5 envelopes to the following addresses:

..1) Jason R
3702 Werner Ave.
Austin, TX 78722

..2) J Arenas
1600 Malibu
Carrollton, TX 75006

..3) Richonda S
CMR 402 BOX 274
APO, AE 09180

..4) J Roth
2901 Barton Skyway ..3406
Austin, TX 78746

..5)Jesse James
1778 Swift Ave.

Ventura, Ca 93003

STEP 2: Now take the ..1 name off the list that you see above, move the other names up (5 becomes 4, 4 becomes 3, etc...) and add YOUR Name as number 5 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 32,000+) All you need is 200, but remember, the more you post, the more money you make!

This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again.

PLEASE REMEMBER that this program remains successful because of the honesty and integrity of the participants and by their carefully adhering to the directions.
Look at it this way. If you are of integrity, the program will continue and the money that so many others have received will come your way.

NOTE:
You may want to retain every name and address sent to you, either on a computer or hard copy and keep the notes people send you. This VERIFIES that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft.)
So, as each post is downloaded and the directions carefully followed, five members will be reimbursed for their participation as a List Developer with one dollar each.
Your name will move up the list geometrically so that when your name reaches the ..1 position you will be receiving thousands of dollars in CASH!!!
What an opportunity for only $5.00 ($1.00 for each of the first five people listed above)
Send it now, add your own name to the list and you're in business!

---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS----------
Step 1)
You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your cursor to the bottom of this document, and select 'copy' from the edit menu. This will copy the
entire letter into the computer's memory.
Step 2)
Open a blank 'notepad' file and place your cursor at the top of the blank page. From the 'edit' menu select 'paste'. This will paste a copy of the letter into notepad so that you can add your name to the list.
Step 3) Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.
Step 4)
Use Netscape or Internet explorer and try searching for various

newsgroups (on-line forums, message boards, chat sites, discussions, etc.)
Step 5)
Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this
will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button.
You're done with your first one!
Congratulations...THAT'S IT!
All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!
REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200
That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount of mail you will receive. If you wish to stay anonymous, you can invent a name to use, as long as the postman will deliver it.
JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.
Now the WHY part:
Out of 200 postings, say I receive only 5 replies (a very low example). So then I made $5.00 with my name at ..5 on the letter.
Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at ..5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at ..4 and only 5 replies each, I will bring in an additional $125.00!
Now, those 125 persons turn around and post the MINIMUM 200 with my name at ..3 and only receive 5 replies each, I will make an additional $626.00!
OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at ..2 and they each only receive 5 replies, that just made me $3,125.00!!!
Those 3,125 persons will all deliver this message to 200 newsgroups with my name at ..1 and if still ONLY 5 persons per 200 newsgroups react I will receive $15,625,00!
With an original investment of only $5.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $5.00 to names on the list, putting your name at number 5 again. And start posting again.
The thing to remember is do you realize that thousands of people all over the world are joining the internet and reading these articles everyday?, JUST LIKE YOU are now!!
So, can you afford $5.00 and see if it really works?? I think so...
People have said, "what if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are tons of new honest users and new honest people who are joining the internet and newsgroups everyday and are willing to give it a try?
Estimates are at 20,000 to 50,000 new users, every day, with thousands

of those joining the actual internet.
Remember, play FAIRLY and HONESTLY and this will really work!!!

I never made the argument that Christians should rise up against Islam, you
did. You're as fond of attacking Christians as anything else you don't
understand, but we could leave that out of the discussion easily, as it just
gets you more confused and doesn't answer the problem that I stated, which
was:

> >>>We have not declared war on the nation of islam, but we should, because
they
> >>>have long ago declared war on the west and all of our tenets of free
> >>>religion, free economies and forms of self-government.

Read that to yourself a few times, Tom.

I may have a big mouth, but I will not apologize for the beliefs and fundamentals that made western life the best the world has ever known. It is also the only system of beliefs that sacrifices our sons and daughters to free others from tyranny, and to educate and promote free trade that allows employment of all in an honest living. That saps like you will argue everything Americans say or do is more evidence that we are truly a divided country. But what divides us in not what the muslims want to kill us for, and you are too much of an ass to see that you will be as dead a sap-sucker as I will be a patriot, unless we agree on the definition of islam as evil. That has nothing whatsoever to do with christianity or any other religion. It is reality.

Other places your stereotype darts landed were also wrong; I grew up in the north-east, have a bachelor of science from a northern school (minor in poli-sci), and was also educated in West Germany where I was an exchange student for a year. I traveled all over europe then and many times later, not counting my service as a launch operations supervisor aboard a ballistic missile sub, forward deployed in scotland. I'm well aware of the atrocities of nazi germany, and its another mark of your ignorance that you could assume you know what my education and experience was there. Want to teach me some more about who has nuclear weapons next? My "thick southern skull" is so ripe for your vast knowledge of tripe, tom.

Islam and its muslim cronies that have been the cause of crusades in the past and are causing history to repeat itself now. I never heard any tv preacher say that, it's as obvious as the day is light. Maybe you folks in california just don't appreciate what it felt like to have one plane load of muslim suicide-bombers fly over you and then crash in your state, and have another one headed for the same place, fall a little short. Or hear about how two of the same bombers were in your city for two weeks scoping out weak points in your seaport and military installations. But virginians do remember that it was the city council of berkley california that made several demands to the u.s. government to stop bombing japan even as we were losing thousands of young marines and sailors every week to push the japanee out of the occupied territories of the pacific. Good thing I don't believe in stereotypes like you do, or else you and most of your state would be given one-way tickets out.

Hi Cecil,

"the sacking"? 1204 or 1453? Pretty ruthless, but don't recall the christian defenders using suicide bomber tactics, then or ever. I'll take Richard's story of that young marine's comments (was it an adaptation of remarks from the movie "Patton"?) about not being keen to die for his country, but looking forward to fighting for it (making the other guy die for his country).

2665. Several questions about mobile HF antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-19 12:30:03 UTC
From: "Joe S." <nobody@nowhere.net>
Message-ID: <cv7bga022ik@news1.newsguy.com>
Source record: 81804

I am considering purchasing an FT-857D and mobile antenna to install in/on my old Nissan pickup. My work shift is 0400-1300 or 0500-1400 M-F with a 35-minute commute along an interstate highway and I would like to spend the time operating HF from the Mississippi Gulf Coast.

While the rig is no problem, the antenna is. I have been reading the postings to this NG about mobile HF antennas and the opinions and experience are all over the map.

For simplicity, I'm looking at the Yaesu ATAS-120 -- I think that's the model number -- screwdriver antenna for the 857D. I read a lot of references to adding a whip to the top of the screwdriver antenna. Am I correct that I will need to add a whip to the ATAS-120, or, am I misreading something here?

If 75-meter operation results in an antenna that whips trees and bangs into the overhead at gas stations, I would simply forego 75 and operate 40 and up.

Would you folks be so kinds as to explain:
-- Your experience with the ATAS-120.
-- How did you mount your ATAS-120 or similar screwdriver antenna?
-- What's this business about a whip on top of the screwdriver antenna?

I am not the sharpest knife in the drawer so use simple sentences and short words.

Thanks.

--

Joe

> "the sacking"? 1204 or 1453?

The 1204 sacking of the Christian city by Christian
Crusaders during the Fourth Crusade.

"Eventually, the crusaders were victorious, and the citizens of the
city, strangely, at least to western eyes, welcomed them into the city
as usurpers, not as conquerors. The crusaders did not see it this way,
and they inflicted a horrible and savage sacking on Constantinople for
three days, during which many ancient works of art were stolen or
destroyed."

How does one defend those Christian acts?

Most pole mount antennas have a suitable bracket attached that will accept two "U" bolts that usually come with it.

With the pole on the ground, lay the antenna so that the pole top and antenna bottom line up. Using the "U" bolts and any additional hardware that comes with it attach the two together.

If the diameter of the pole is to great for the "U" bolts you may have to make an adapter plate, also unless the pole is of very large diameter you may have to use guy wires to support such a tall system. The guys should form a 45 to 60 degree slope.

Make sure the pole can stand by it's self without bending. My elmer was trying to erect a long pipe to hold a tri-bander with my help. We attached a come along to his tractor and the bottom of the pipe. After much cranking on the come along we stopped to check our progress. When we turned around to look we were presented with a pretzel. The pipe was to soft for the application and the antenna was still on the ground while the base was vertical. ;^)

Islam is no more evil than any other ancient religion, and even if
it were, you couldn't stop it by aping it. As for this wonderful
country, it wasn't built on the principals of ethnic hatred and
genocide (if you leave out what happened to the Native Americans).
You may be from the North East, but your intellect is straight out of
the middle ages, just like that of the people you profess to hate.
It's a good thing most people don't share your views. The U.S. would
quickly deteriorate into a second-rate country of religious fanatics,
ethnic bigots and tribalists making us ripe for exploitation by any
people who were willing to exploit our backwardness.

Caveat Lector wrote:
"A WWII B-24 bomber (Lady Be Good) ran out of fuel because they were not sure of the DF readings."

Too bad they ran out of gas and drash landed in the Libyan desert. The B-24 must have been covered with sand for most of the time because there was still most of it intact to be found.

On April 4, 1943, the Lady Be Good radioed for a directional reading from the high frequency direction finding station at Bernina as the earth was covered with clouds and there were strong winds causing navigational errors. They needed a position fix.

I had breakfast this morning with a WW-2 B-24 pilot who flew in the same area. He said that requests for position fixes were often answered by Germans pretending to be the direction finding facility, and they would intentionally lead the questioners astray.

Joe,
A word about the whip thingy. The ATAS-120 comes with a
whip which is adequate for it's stated band coverages. A
longer whip can allow it to cover lower frequencies. Just
how 'long' the whip gets depends on how much you are willing
to modify your driving habits - lol, as in forget the drive-
through windows, low trees, etc. (more or less typical for the
average 80 meter mobile'er). In general, the bigger, uglier,
and more inconvenient the HF mobile antenna, the 'better' it
works...

Sympathizers of islam? (greek v latin *). Selected dates:

626: Siege of Constantinople by Persians and Avars
674-78: Siege of Constantinople by Arabs
717-18: Second siege of Constantinople by Arabs
1054: Schism between Eastern (Greek) and Western (Latin) Churches *
1097: First crusade
1147: Second Crusade. Normans capture Corfu, Corinth and Thebes
1182: Massacre of Latins in Constantinople *
1204: Capture of Constantinople by Fourth Crusade and establishment of Latin Empire *
1261: Recapture of Constantinople by Nicaean force and end of Latin Empire
1397-1402: Siege of Constantinople by Sultan Bajezid
1422: Murad besieges Constantinople
1453: Turks take Constantinople on May 29.

How do the battles to contain muslims then differ from now?

Islam and the Theology of Power
A Muslim scholar looks at Islamism
http://www.islamfortoday.com/elfadl01.htm

El Fadl says that Islamism is at its core a,
... supremacist puritanism that compensates for feelings of defeat,

disempowerment and alienation with a distinct sense of self-righteous arrogance vis-&#65533;-vis the nondescript "other" -- whether the other is the West, non-believers in general or even Muslims of a different sect and Muslim women. In this sense, it is accurate to describe this widespread modern trend as supremacist, for it sees the world from the perspective of stations of merit and extreme polarization.

Read the whole thing. It's eye opening.

Read the whole Bible. It's eye opening. Particularly
the part advocating stoning to death all adulterers.
Thou shalt not kill (except adulterers).

Islam, Christianity, and Judaism all have the identical
God-head and share many books of the Bible. Allah,
Jehovah, and Yahweh are all the same divine entity,
a member of the Elohim (plural gods) clan. When Jesus
prayed in Aramaic, he prayed to Allah. Under Islam,
Jesus is considered to have been a great prophet.
Jesus' image hangs in many Islamic mosques.

Stirring up hatred for Islam is just as evil as stirring
up hatred for Christianity, Judaism, or any other religion.
It is definitely NOT what Jesus taught so you are not
following your religious teachings any better than
the Islamic terrorists are following their religious
teachings. Shame on you.

2683. Re: Doublet Length: More is better?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-19 19:24:32 UTC
From: Dan <starkenburg.remove@this.sio.midco.net>
Message-ID: <Rb-dnT9umNHtD4rfRVn-2Q@midco.net>
Source record: 81821

More is not always better. As far as performance goes, some have suggested that your antenna pattern can have more lobes (a bad thing) if you went with the 100' of wire vs. the 88'. Having a very lobey pattern makes it hard to determine where your signal is actually going, whereas having less lobes usually means your signal will radiate at 90 degree angles to the doublet antenna.

See an article describing this at:
http://www.cebik.com/aledz.html

In the article, the author thinks 44' is the optimal length for a 40-10M antenna and 88' is the optimal length for an 80-20M antenna, assuming you want to maintain an accurate radiation pattern.

Source record: 81722
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna

I installed a Cushcraft ARX2B Ringo Ranger II yesterday. It's on a 10' mast on a rooftop tripod. The measurements given in the manual for assembling the antenna for a specific frequency were right on the mark. I used the dimensions for 147MHz and my MFJ-259B showed the "sweet spot" to be 146.88MHz. SWR bandwidth is a bit narrower than I'd prefer, but it is a very usable antenna for the 2M FM application.

As far as performance.... I cannot complain at this point. I am able to bring up a repeater 80 miles away half scale. My wife and I tried out simplex today and it performed well. Previously I've owned the Diamond X50A and CP22E antennas, as well as a slew of groundplane and J-Pole antennas. Based on the performance I've experienced so far, it appears the ARX2B is better than most, as it should be because it's a 5/8 wave x 3 (vs. a 1/4 wave x 3 for the X50A and a 5/8 wave x 2 for the CP22E).

I'd suggest you have the guys in your area double check their assembly as I'd tend to think they did something wrong if they're comparing the performance to a dummy load. The antenna has something like 40 pieces out of the box.... plus a few different adjustment points (middle and bottom coils, plus the length of the antenna between coils).... so there is a lot that could be done wrong with the antenna. Also, I'd tend to think the "weak point" of the antenna would be the run of coax that connects the radials to the bottom coil, so that would also be a good place to look.

2687. *post 100* >> GOOD NEWS! - Over 2000 years ago Jesus Christ suffered and died on a cross and rose from the dead so that we can be forgiven of our sins(misdeeds) and have a home in Heaven when this life has ended. Most people just don't know how to ask Jesus Christ into their hearts. Heres how...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-19 20:27:57 UTC
From: RL_Grossi_2005@sbcglobal.net
Message-ID: <1108844877.514609.110300@z14g2000cwz.googlegroups.com>
Source record: 81724

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

If you decide to wait till later you may die before you get another chance to be saved because none of us knows exactly when we will die.

This means that if we die without trusting in Jesus Christ as our Lord and Saviour we will be forever separated from the love of God in a place called Hell. This place called Hell is a place of eternal torment, suffering, pain and agony for all those who reject Jesus Christ.

Choose Jesus Christ today and you will have peace in your life now and forever.

Have a great day!

It was a miracle that I even looked at this post given the topic, but I did and found that you were replying to me under a subject to which I didn't post (i.e. you changed it).

It's good that you're satisfied with the Ringo Ranger II and that they have a defender somewhere (you don't own stock in the company, do you?). But I know that my experience was not from a bad install (37 years of communications experience now) and I doubt that so many others all did it wrong. Maybe you messed up with your other antennas and that made the ringo look better.

I stated facts to you and no matter your likes or dislikes what I stated shall remain fact.

Allow me to introduce you to the New Testament, which while acknolwedging the history and covenants formed in most of the Old Testament, includes the spoken words of the Lord Jesus Christ, the one and only Savior. Taken as a whole, these testaments together form the basis for Christianity.

I don't need to bring whatever religion (or lack thereof in 90% of liberals and probably 50% of conservatives today) is followed in the United States in order to argue for the destruction of Islam, before it destroys us. And if you do insist on bringing up Christianity and calling me shameful or without belief of the teachings of Christ, then please cite where you think Christ wanted us to succumb to evil or murderous practice, whether on the highway or by foreign invasion. Some duties He said were the job of the state, and that is where our influence comes into play, as we are part of the state in any system of self government. Bringing a highwayman to the magistrate (dead or alive), foreign or domestic terrorists to trial (same condition applies), or defeating a whole army of evil (read MUSLIM, socialist, communist, etc) is the job of the state. I was a volunteer then and now for the "state". And I am still a Christian, though it is no business of yours whether a religion is the background for the #1 law of nature or not: self preservation. As a

people, as a country, and as any of the freely practiced religions (including none at all for atheists) we are at war with Islam, whether you admit this or not. There is enough evidence to convince a misbehaving child of this fact, but you can certainly set a new standard for misbehavior there - as long as you stay out of our way while the rest of us survive.

73, Jack

I see that the subject was changed before. The first 3 messages I replied to were "The HIGHER the BETTER" then 3 of these that someone changed and I didn't notice, then one more "higher" then back to these. I didn't notice the change because they were in the thread together.

I am looking to use a piece of PVC as the center insulator of a vertical dipole I'm planning to put up. Anyone know the insulating characteristics of this stuff? It's not going to conduct significantly @ hf when wet?? Thanks for the help.

It works fine.
I used a short piece of pvc to connect 2 pieces of aluminum conduit.
I fed the coax thru one end of the alum conduit to have a vertical dipole
fed from inside where the 3 pieces come together

2696. *post 101* >> GOOD NEWS! - Over 2000 years ago Jesus Christ suffered and died on a cross and rose from the dead so that we can be forgiven of our sins(misdeeds) and have a home in Heaven when this life has ended. Most people just don't know how to ask Jesus Christ into their hearts. Heres how...

Newsgroup: rec.radio.amateur.antenna

Source record: 81734

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

If you decide to wait till later you may die before you get another chance to be saved because none of us knows exactly when we will die.

This means that if we die without trusting in Jesus Christ as our Lord and Saviour we will be forever separated from the love of God in a place called Hell. This place called Hell is a place of eternal torment, suffering, pain and agony for all those who reject Jesus Christ.

Choose Jesus Christ today and you will have peace in your life now and forever.

Have a great day!

Hey Charles!

I looked you up and a lot is explained. I thought you had died or something.
I hadn't seen you trolling on the firewall newsgroups like you used to and
your AB7SL web site was gone.

It's been a long time.

Believe it or not, I'm glad to see that you are alive and kicking and not as
caustic as you used to be.

I really do mean it.

God Bless You!

One of the fastest growing religions in the U.S. today is Islam. Muslims participate in all parts of society, including national defense. Like it or not, Jack, your jihad against Islam is doomed to failure, just as your sick version of Christianity is. The Wahhabists of Saudi Arabia are certainly loathsome people, but you're not doing the world, or yourself, a favor by patterning your behavior after them.

Is a loop antenna a way to get a "long" antenna in limited space? I am having a hard time finding detailed information on loop antennas. I have seen some references to using a long wire, but making several loops which requires much less space.

And the second question is about feed lines. Could I connect 450 ohm ladder line to the ends of the loop(s) and then run it to a balanced tuner in my shack? Most references I have seen about loop antennas talk about capacitors installed at the loop.

Any insight will be appreciated.

Thanks, jimbo

Yes, but there are some Christian-Muslim-Hindu-Jewish fanatics
who want to regress to a pre-scientific age because they think
their people were better off back then.

Hi OM,

That is one way, but if you mean making several turns (loops?) the
topic will become muddied by what is meant by "loops."

>And the second question is about feed lines. Could I connect 450 ohm
>ladder line to the ends of the loop(s) and then run it to a balanced

Sure, no big deal, you run the same assortment of difficulties and
benefits, just at different frequencies.

>Most references I have seen about loop antennas talk
>about capacitors installed at the loop.

Ah! Now we are back in the mud of discussion. Those are SMALL loops.
You know, like 1M across.

So, to avoid further difficulties, just what size of a loop are you
thinking? Loop OR dipole, offering the prospective size makes a
considerable difference to the accuracy of responses.

Thanks for your reply.

Well, for example, if I wanted a chance on 40-160 meters, I would need
a fairly long dipole, maybe 80 feet on each "wing". But maybe a square
"loop" with four turns only 10 feet on a side would also work?

I have three yagi's that I want to mount on one tower.
1)Hy-Gain TH3-MK3 three element HF tribander
2)Cushcraft 32-19 nineteen element Two meter yagi
3)Cushcraft A50-3S three element six meter beam
I installed a 40' Glen Martin with hazier last fall and I want to place these three antennas on a mast at the top of this tower. My question is, How far above the tower should the first antenna be, is there any particular order to mounting, how far apart should these antennas be from each other? I'm using Kevlar guys, so they shouldn't cause any problems. The tower is grounded at all three legs.
TIA
Harry

Hi Tom,

Most of our (make that all) problems do not come from religious
simpletons who have THE answer (usually involving genocide).

No, we have big time problems with administration clowns who want to
poke a stick in their eye, and then spout reams of denial about how
well they are "defending" us from their inflamed passion.

The latest news out of the white house Big Top press briefing room is
the administration's planted "reporter," "Jeff Gannon," who worked for
the fake news organization "Talon News." Hired by the ministry of
information he has the unique qualifications of being a $200-an-hour
gay prostitute.

Should we visit "Family Values" now?

Hi OM,

Anything will work, if only to boil an egg. Your problem with a small loop (and for 160M this so constitutes one) is in the proportion of losses. If you do your absolute best, you may enjoy 20dB down from a full size design. If you do better, the loss may not be that bad. Nearly every successful 160M design that has been crowed about here was a vertical.

Efficiency is correlated to area, not windings. We've had design contests here in attempts to crush as much wire into the smallest footprint to achieve parity with a full size design. As I recall, a half sized antenna was about as good as it got before you went over the cliff of diminishing returns.

2706. *post 101* >> GOOD NEWS! - Over 2000 years ago Jesus Christ suffered and died on a cross and rose from the dead so that we can be forgiven of our sins(misdeeds) and have a home in Heaven when this life has ended. Most people just don't know how to ask Jesus Christ into their hearts. Heres how...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-20 02:28:22 UTC
From: RL_Grossi_2005@sbcglobal.net
Message-ID: <1108866502.955823.94660@z14g2000cwz.googlegroups.com>
Source record: 81743

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

If you decide to wait till later you may die before you get another chance to be saved because none of us knows exactly when we will die.

This means that if we die without trusting in Jesus Christ as our Lord and Saviour we will be forever separated from the love of God in a place called Hell. This place called Hell is a place of eternal torment, suffering, pain and agony for all those who reject Jesus Christ.

Choose Jesus Christ today and you will have peace in your life now and forever.

Have a great day!

David,

No, I don't have stock in Cushcraft, nor would I want to. Cushcraft seems to be the MFJ of antenna companies - they make an inexpensive product and, unfortunately, they have their share of flops. I guess we have differing opinions as to whether the ARX2B is a flop or not.

I used the same rooftop tripod, same mast, and same feedline for the antenna comparisons. Like I said, the antenna has only been up for a couple days now but all indications at this time are that it is performing well.

If cost were not a factor, I would've gone with a DB224, beam/rotor assembly, or perhaps even a Hustler G7-144, and I'm sure performance would be better. However, for the $60 I paid for antenna I can't complain.

Interesting enough, if you check out the reviews of the antenna on eHam (http://www.eham.net/reviews/detail/4437), you'll see that it earned a respectible 4.0/5 rating. Of those that didn't give it a perfect score, one cited poor instructions, one cited a problem with the phasing cable (which appeared to be related to an installation issue), and only one person cited issues with the actual performance of the antenna (out of eight reviews).

73,
Dan

EZNEC predicts the pattern very well. And the reason Mr. Varney,
G5RV, chose 102 ft. for his 20m antenna was to take advantage
of the beautiful cloverleaf pattern that allows me to hit
Europe, Central/South America, New Zealand and the Far East
with 10 dBi lobes without rotating my antenna. Quite often,
my fixed G5RV beats my rotatable dipole.

It will work great. If you want to test it, microwave a piece of the
material for 1 minute. IF it gets very warm, you may want a different
material. The white pvc should work as well as you need and then
some.

Single turn loops are more popular than multi-turn loops
because they are more efficient. Small loops are about
0.1 wavelength long usually resonated with a vacuum
capacitor.

Source record: 81753

Good News!

Do you know how simple it is to go to Heaven after this life has ended?

The good news is that God came from Heaven to earth in the person of Jesus Christ over 2000 years ago and died for our past, present and future sins(misdeeds). He was born in the land of Israel supernaturally to a virgin Jewish woman named Mary. He lived a sinless life for thirty-three years and then sacrificed His sinless blood and died on a cross to pay the death penalty for our sins.

After Jesus died He rose from the dead three days later as He said He would. The Holy Bible also tells us that Jesus Christ ascended into Heaven and that all who accept Him as their Lord and Saviour will live forever with Him in Heaven where there is no more death, sorrow, sickness and pain.

The Holy Bible very clearly explains how simple it is to be saved and on your way to Heaven, "For if you confess with your mouth, "Jesus is Lord," and believe in your heart that God raised him from the dead, you WILL BE SAVED." (Romans 10:9)

You can be saved right now and on your way to Heaven if you will open your heart to Jesus and pray the following prayer:

Dear Jesus Christ, I want to be saved so that I can have a home in Heaven when I die. I agree with You that I am a sinner. I believe You love me and want to save me. I believe that You bled and died on the cross to pay the penalty for my sins. I believe that You rose from the dead. Please forgive my sins and come into my heart and be my Lord and Saviour. Thank You Lord Jesus Christ for forgiving me and saving me through Your merciful grace. Amen.

You are now a Christian if you said the prayer and allowed God to save you. Welcome to the family of God.

If you decide to wait till later you may die before you get another chance to be saved because none of us knows exactly when we will die.

This means that if we die without trusting in Jesus Christ as our Lord and Saviour we will be forever separated from the love of God in a place called Hell. This place called Hell is a place of eternal torment, suffering, pain and agony for all those who reject Jesus Christ.

Choose Jesus Christ today and you will have peace in your life now and forever.

Have a great day!

Hi Cecil,
me too. And we've got a lot to be scared of.
All it takes is for a religious nut to take over the
government of the U.S., or India, or Pakistan, or
North Korea, or Israel, etc., and we'd be in for it.

Reg, G4FGQ wrote:
"It`s purely a matter of Spherical Geometry."
The ARRL agrees with Reg. The 19th edition of the ARRL Antenna Book on page 23-24 gives path distance versus vertical wave angle for a one-hop transmission using the F2 layer in Fig 23. Of course these are only based on a variable reflecting layer height.

For 500 miles, 40 to 70 degrees.

For 1000 miles, 20 to 35 degrees.

For 1500 miles, 10 to 22 degrees.

For 2000 miles, 4 to 15 degrees.

For 2500 miles, less than 8 degrees.

Neither elevation nor azimuth angles are exact as the wave is subject to detours but it helps to have an idea of the usual best angles.

Best regards, Richard Harrison, KB5WZI

Source record: 81763

hey harry
i recently put up 3 long boomed yagis
a M2 6M7 which is 7eles on a 27ft boom 6 meters
KLM 16LBX 16ele on a 28ft boom 2 meters
KLM 30LBX 30ele 70cm on a 22ft boom
and what i did is mounted the 6 meters at the top of the tower 40ft and
stacked the others 5ft apart
and they work fine i do get into the front end of the differnt radios
when i transmit so i think i got them a bit close together but it hasnt
hurt the performance or the SWR of any of the antennas
in your case i think i would put the HF tribander at the bottom of the
stack then 5ft above that i would mount the long boomed 2 meter yagi
then 5ft from it the 6 meter antenna
usually i would stack them the higher in freq the higher on the mast but
since the 2 meter yagi has a lot longer boom i would put it in the
middle to you have room for the boom supports
good luck

I started the topic. It was set in WW2 because I see so much about
RDF at that time. i realize it has to have improved by now but the
heart of the question is 'since it was possible to be accurate then,
why can't hams accurately do it today?'

I am thoroughly enjoying this thread.

Thank you to ALL that have replied.

http://www.qsl.net/w3ff/antenna_design.htm

One of the favorite portable antennas of the HFPack group
(http://www.qsl.net/hfpack/freq.html#REGIONAL) is the BuddiPole
antenna. There are commercial and home-brew versions (see above
links). I built one. The homebrew is pretty flimsy, but fun to build
and play with.

Good luck and have fun. Hope to see you on the HFPack frequencies.

2728. Re: Antenna spacing?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-20 16:03:23 UTC
From: Crazy George <munsch@atglobal.net>
Message-ID: <4218b7f8_1@news1.prserv.net>
Source record: 81765

Harry:

Here is the general rule of thumb way to approach this requirement. With the booms aligned, each antenna only "sees" a
lower frequency (larger) antenna. So start at the top with the 2 meter antenna. It needs to be a half wavelength at 2
(~40 inches) from the next thing. And so on to the others. The 6 meter should be about 100 inches from the tribander,
and the tribander doesn't care. It looks mechanically clumsy, but putting the 2 meter half way between the tribander on
the bottom and the six meter on top with the 6 and triband 100 inches apart is close to the best compact arrangement.

>I am thoroughly enjoying this thread.

There is really two types of DF. Long haul and close in. The close in type which generally uses some sort of null loop from a mobile platform (such as a car or on foot) is what is generally used in "fox hunting" types of transmitter hunts by hams and other hobbists. By extension, the military also use some of this close in technique from tactical aircraft although the technology is different.

Long haul, such as was employed in WW II for sub hunting in the Atlantic was done from fixed shore facilities for the most part which exchanged their lines of bearings via a dedicated secure network.

Close in DF is accurate only in the sense that the hunter can usually move in close to the target to the point that they can actually see the antenna.

Long Haul DF cannot pinpoint a target. Long haul DF stations have known error tolerances and so-call "fixes" are stated with circular or elliptical errors of probabilities. So one might DF a transmitter operating in the Atlantic from shore stations around the perimeter of the Atlantic. The fix will be stated with some degree of tolerance such as there is a 90% chance the target is within an ellipse 100 miles long and 50 miles wide and a 10% chance it is within a 15 by 5 miles area within that larger circle. This is of course still many hundreds or even thousands of sqare miles to hunt for a target. I do not know what technology the Allies used during WW II for their HFDF or what sort of accuracy they achieved.

In a WW II scenario, it would be an important intelligence fact if one could discern if a target was near Bermuda or if it was near the Azores. Then a destroyer or subchaser or small carrier with aircraft would have to be dispatched to try to find it if it were on the

surface. Allied sub hunting was successful because German doctrine called for frequent situation reports from submarines to shore commands in France and Germany.

US submarine operations in the Pacific were more successful in a defensive perspective since they usually operated with a doctrine of radio silence and only rarely sent messages to shore station or to each other. It must be remembered that WW II era subs generally operated on the surface and submerged mostly for attack or self protection. The German sub commanders were in essence victims of Doenitz' tendency to micromanage and they sustained casualty rates of 70% or greater. US sub forces by comparison had casualty rates of 15% which was still among the highest among US forces. Germany had roughly four or five times as many submarines as did the US.

[Folks unfamiliar with WW II history must also note that the US had almost no sub forces in the Atlantic since Germany had only a very small surface Navy and almost no coastal or open ocean shipping. A sub of that era was a poor platform to wage war against another submarine. Japan, being an island, was dependant upon ocean shipping for supplies and so was more of a natural target for anti-shipping submarine operations. US subs of course also attacked combatants, but many of those combatants were escorts for shipping convoys. Virtually all US submarines operated in the Pacific Theater. The Brits did have some submarine operations in the Atlantic.]

The emphasis should be on the "almost"!
Germamy began the war with 3 formidable "pocket battleships" as I recall. There were American submarines in the Atlantic. Headquarters are at New London, CT. My brother was a WW-2 U.S. Navy submarine officer. His boat was stationed in the Atlantic operating from the U.S. Virgin Islands. He managed a leave home by snagging rides on Catalina flying boats conducting anti-submarine patrols in the Atlantic. He observed real anti-submarine actions while a passenger aboard the Catalinas. My brother was assigned to a new ship from its keel laying. He took it through the Panama Canal to the Pacific where after several missions it became a craft on permanent patrol as the result of enemy action with no known surviors. His family misses him.

Best regards, Richard Harrison, KB5WZI

I use a hustler quick disconnect. When I go through a drive through, I take my antenna off, and lay it on the roof until I get through, and then I get out and stick it back on. That disconnect also makes it much faster to change bands...My coil is so high, there is no way you can reach it without taking the antenna off.. Without the disconnect, you have to screw em in and out...Takes a lot more time. MK

>I installed a 40' Glen Martin with hazier last fall and I want to place
>these three antennas on a mast at the top of this tower. My question is,
>.............................>snipped<.....................

I have 28Ft (from ground level) Rohn 25. My set up for all modes on
6/2/70cm is as follows.

Top going down:

Top Arrow OSJ146/440 Jpole
Just below is a 215WB (15element CC)
41" below that is a 5Element UHF (horizontal Arrow 440-5s)
42" below the UHF is the Arrow 52-4s (6m 4 element beam)
(total distance between the 2m and 6m beams is 81".)

The combined tower and mast height puts the 6m beam more than
14ft higher than the roof of the house and exactly 30ft above ground.
My tower is bracketed to the side of a low ranch house.

At the 25ft level of the tower is a lanyard for raising and lowering
the tower end of wire antennas. Those wires extend to trees and poles
elsewhere on the property. I set up two of these on two of the legs
of the tower. One carries my 24ft EDZ for 6m aimed SW
and the other has a general use wire running NNW for HF listening.

I also have vertical dipole for 6m on the south leg at about 20ft
(center of the antenna) of of the tower for local 6m FM use and on the
north leg a CuCactus for 2m/70cm (15ft to the base of it) for local
use.

This arrangement is optimal for the 2m and 6m and appears effective
for the UHF as well. The goal was to keep the mast extending above
the tapered section (25AG) to under 8ft as I only had an 11ft mast.

Seems to be effective for F2 and Es and to the limits of 4elements
on 6m for tropo. The other effect is the J at the top is both
effective due to height and also not having radials doesn't interfere
with the 215WB just below it. The UHF was installed for later use
as I only have limited UHF capability and I expect to replace it with
something in the 11-15 element range when capability expands.

The actual spelling is Wullenweber. I have a photo of the HFDF Station in Masset, BC where I was Operations Officer at one time -- you can find it if you go to my website at http://members.shaw.ca/finkirv4/links.htm

If you include all the masts, guys, antenna elements, and such it could be construed as a masterpiece of weaving.

Here's a related curiosity:

Dr. David Woolweaver is the Assistant Director of the West Gulf Div. of the ARRL. I discussed the name at length with
him several years ago, although he was previously unaware of the antenna design connotation. He told me there is also a
small town in Germany named Wullenweber. You will find no authoritative information on the derivation of the name for
the CDAA. Anyone who tells you different is lying. The few Germans still living at the end of the war who could be
identified as having been associated with the project either didn't know or refused to say. But that never stopped
speculation.

Buck:

A difficult to find but accurate book which answers your question about WW2 is "Secret Weapon" by Kathleen Broome
Williams published by Naval Institute Press. I no longer have a copy at hand, so I cannot quote figures for claimed
accuracy.

The reason Hams can't do this are two-fold:
1. Space
2. Money.

A good HF Adcock of WW2 design requires 10 or more acres to be accurate and is expensive to build because of the
mechanical accuracy involved. The 1960s vintage CDAA systems discussed typically require 40 acres, and the last
replacement cost figure I saw was over $100 million. The smaller "Pusher" systems are difficult to pin down price wise,
as they are out of production, but are still in the million dollar range for a prepared site, which for them is still
several acres. Measured sensitivity of the Pusher is 9 or 10 dB poorer than the full size CDAA, and the accuracy tends
to be less, although in both cases instantaneous accuracy is dependent on propagation and not system accuracy. Mobile
systems can be much less expensive, but to deploy one, you need to already know where the target is, more or less. By
the way, the last FCC mobile system I saw was in an unmarked Chrysler sedan with NO obvious external antennas.

And, even with the best equipment, a one degree accuracy (rare) still produces a large area of uncertainty at the target
distance. That is the key to understanding this. At a mile or a few blocks distance, a one degree accuracy will get
you to the target. At 2,000 miles, it just tells you which ocean the target is in.

I knew I had a better JPEG of it around here somewhere:

http://jonz.net/W3DHJ/images/W3DHJ_Tower.jpeg

From the top - down: CC A50-3S , an old CC 215WB , and the CC A3S.
That's a home-brew 2M vertical on the forward boom of the A3S.

Sigh... It all comes down in a couple of months.
Moving to a new Grid Square....

Crazy George wrote:
"The reason Hams can`t do this are two-fold:
1. Space
2. Money."

That`s usually true.

I don`e think anyone has mentioned Doppler or Quasi-Doppler DF systems yet. I`ve seen hams using them but I have no experience with them.

Servo Corporation of America claims to have supplied over 350 Quasi-Doppler radio direction finding systems to the U.S. FAA and they are used in airports throughout the U.S.A.

The angle at which a VHF signal wavefront passes over a small forest of antenna elements is determined to give a bearing toward the transmitter.

It has been generally found that for radio direction finding that the larger the antenna, the better the performance.. But, in the case of two spaced antennas, the spacing must not exceed 1/2-wavelength to avoid ambiguities. Peak error from an Adcocvk Array is 11.4 degrees, says Servo Corp. Their Doppler Systems, they say, are much better.

I see what I suppose are Doppler antenna systems on the trunk lids of police cars.

Best regards, Richard Harrison, KB5WZI

Regarding antenners, thats right,antennas.
Plenty of listings for various gains achieved with antennas
but I have not seen any similar listings for F/R and F/B.
Is there any around so I can see what can be or has been attained or
is blocking of rear signals of little consequence for todays hams. I can see
that being true
for when the band has just opened and propagation has not opened to the rear
or
with net operations so perhaps gain is every thing after all.
It is my opinion that if interest/efforts are increased first in deflecting
the rear action to the
front first and thereby INCREASING the front lobe width there will be more
opportunities
for increasing gains without the side lobes and narrow forward lobes that
accompany Yagi's.
as well as shorter booms. (more deflectors/reflectors perhaps)
(no religeous, porno or genocide preaching please, fighting to see which is
best
could take place on boat anchor nets to see which has taken position of the
lowest level)

Actually, we have been skating around the real answer to all this. HF systems which are presently being deployed are
true mathematical interferometers, and if anyone has the computer expertise to write the computer programs to build one,
I can supply the RF design information. For 40 meters and down, this would require only a minimal antenna footprint,
local reradiators can be calculated out, and the rf and processing hardware would be surprisingly simple. I would be
happy to collaborate with anyone seriously interested in constructing one, but you better be ready to convince me you
can do high level programming. And based on previous designs, expect to invest about 4,000 hours in programming.

Danny, K6MHE wrote:
"I wonder what his 6 dB gain is"

There is a "Super J" antenna on page 16-27 of the 19th edition of the "ARRL Antenna Book". The book says the two stacked 1/2-wave collinear elements provide about 6 dB gain over a 1/4-wave whip antenna and about 3 dB gain over a 5/8-wave antenna.

I won`t speculate that you actually get more gain from (2) stacked 5/8-wave sections, but it`s possible. Maybe 3 dB more, like a single 5/8-wave over a single 1/4-wave.

6 dB over a 1/4-wave whip is 8.14 dBi.
The 1/4-wave whip has a gain of 2.14 dBi

Hi Art

In my experience (or maybe its just anecdotal) F/B ratios are very
frequency dependent for high dB numbers. You might for example get 28dB
F/B on 14.100 but it may drop to 15dB 100kHz away. The forward gain in
this case doesnt change much at all. How would you then advertise this
except by a graph?

Keep in mind also that F/B is expressed in a specific direction. 5-10
degrees off that and you will see the numbers fall off.

Max F/B rarely occurs at max forward gain...

Front to side is also good for attenuating signals you dont want.
(Assuming horiz polarisation)

If I was tackling this as a project I'd start defining some parameters
like 3dB beamwidth and the maximum unwanted lobe figures. Then plug it
into a modeling program (like 4nec2) I havent played much with modelling
but I assume that the optimising tools could do the trial and error
calcs for you. You are aiming for an antenna with moderate forward gain
but as low as possible radiation/reception in other directions..

In fact if you havent tried modelling it is well worth it just to see
the effect on the patterns.

You can also tune a (yagi/quad) reflector remotely if you want to peak
the F/B

Probably not what you were after sorry...

Cheers Bob VK2YQA (In Oz...)

Hi
I am building an rf transmitter for a short range data link at 433MHZ
and am almost done, but I would like to understand better exactly what
I am seeing with regard to antenna performance.

All technical notes I have read recommend a 1/4 wave whip over ground
plane as offering the best performance, statements like: "Best range
is achieved with either a straight piece of wire, rod or PCB track @
1/4 wavelength over a ground plane", I understand many factors effect
performance however I have found that a "bent" 1/2 wavelength length
of wire offers better performance.

If I use a 1/4 wavelength I need (due to case requirements) to have
two 90 degree bends in it (feed -> up, across, up).
If I use a 1/2 wavelength I need to run it once around the (plastic)
case (feed -> up, around the case, up).

I hope this makes some sense, anyway I have found the 1/2 wave is less
effected by polarisation and offers generally better performance.
However while more ground plane may help a 1/4 wave it seems to hinder
the 1/2 wave, I guess because it shields the loop around the case?

Regards

A 1/4 wavelength antenna really needs to be straight and at right angles to
the ground plane. That is probably why the 1/2 wavelength antenna works
better in your case.

I would make the grandiose statement that since you are bending the wire
it no longer exhibits the performance of a "standard" 1/4 or 1/2 wave
antenna. I would suggest that if you indeed made a 1/4 wave GP that
protruded from the box surface (with a suitable counterpoise) it would
outperform the 1/2 wave bent one..

Assuming you have to put the antenna inside the box or wrapped around it
I suggest you look into tuning it with some C and/or L. In that case you
would construct the antenna to fit your case parameters and adjust the
matching for best radiation. Keep in mind that the C/L tuning components
could be lengths of coax and open feeder/wire. (because of the high
operating freq)

A 1/4 wave antenna will match to a low impedance, unbalanced. A 1/2 wave
dipole will match to a low impedance, balanced. A 1/2 wave piece of wire
fed at the end will match to a high impedance.

What kind of circuit are you using for your output?

Thanks,
Rich

It should also be mentioned that the front/back ratio is different at various elevation angles. You won't get the free-space f/b ratio in practice at most elevation angles. This is easily seen with modeling software.

Good nulls also depend on a precise balance of strong fields, which all have to be just right in order to add to zero. If any of the various fields is just a little off, the null won't be what you expect -- it'll be shallower and/or in a different direction. It takes only a small difference to change the depth of a deep null by 20 dB or more. That means you can't expect deep nulls to be exactly what a computer program or other calculations predict, because there will inevitably be small differences between the model and the real antenna. Or, for that matter, from one antenna to the next one of the same type, even when built as close to exactly the same as possible. You have the best chance of achieving deep and repeatble nulls with the simplest antennas, like a carefully built and balanced small loop. The larger the number of elements, the larger the number of fields which all have to add together to a value of zero, and the more opportunity there is for variation.

2766. DPDT Coax Switch (sort of)?

Does anyone know of a source for a switch which accepts two incoming PL-259's (A/B) and spits out either A/B or B/A, depending on switch setting. The object is to switch the feedpoints of a rhombic antenna from one end to the other. The two "incoming" lines to the switch are from either end of the rhombic. The two outgoing (from the switch) go to a dummy load and the tuner/transceiver.

TIA.

Joe,

Your best bet is the screwdriver antenna for mobile work. In addition to its ability to cover ALL frequencies, it is more efficient than most all others. A tuner is a bad choice because it doesn't "tune" the antenna. No matter what you do, you will still have a non-resonant radiator sticking up there. The tuner will probably do fine from 10M down to 20M, but it will fall flat on its face on 40 and 80M. JMHO, but if I'm going to spend $200+ for an antenna system, I would want the best-performing antenna system I can get for the money. Tuner/whip combos fall near the bottom of the heap; even the dreaded hamstick (dummy load on a stick) outperforms a tuner on 40/80 Meters.

6 dB over a 1/4-wave whip is 8.14 dBi.
The 1/4-wave whip has a gain of 2.14 dBi ....

The half wave vertical should have that 2.14 dbi gain.
A 1/4 wave ground plane should show about .3 db less...
Or when modeled anyway....

In general, a properly designed dual 5/8 collinear should
have appx 5.1 dbi gain. Or appx 3 dbd.... And yes, that
is slightly more than the dual 1/2 collinear should do.
If a single half wave shows 2.15 dbi, I wonder how adding
a second element can add another 3.85 db gain...???
Myself, I think their gain numbers are a little happy...
Also, in that super J article, the 1/4 wave and 5/8's they
compare to are mobile whips...This would greatly skew any
comparisons with the super J, being it's not a mobile antenna.
IE: make it look better than it really is...
An average elevated 1/4 GP will show appx
1.8 dbi or so...Only about .3 db difference from a 1/2 wave
that is elevated.
Of course, in the real world, the results can vary greatly
due to decoupling, or the lack of, etc...
I'd have to check/model the gain of the super J, but I'm
almost sure it would be less than 5.1 dbi...I'll take a wild
guess and say maybe .6 db less??? MK

Waters made a DPDT coax switch, typically used to bypass an amplifier.
Sorry, don't remember the model #. They can be found FS and FA at the
typical places.

Source record: 81712

You are not going to work all bands portable very well,
unless you are not so portable...IE: the best overall
single antenna for 40-10 would be a 40 meter dipole fed
with ladder line to a tuner.
But you have to drag a tuner around...
Add 80m? Make that a 80m dipole...VHF/UHF? Add a dual
band antenna for those....Again, less portable...
I guess it depends how portable you really wanna be...
I assume that is sort of a backpack rig...
If I were toting a backpack rig, I decide on what bands
I wanted, "within reason", and concentrate on those...
Probably the lightest dipole to cover all bands would
be a 80 dipole, that has insulators to break up the
antenna for all the higher bands..You would have to
manually change jumpers to switch bands, but the antenna
would be very efficient on each band. You could feed it
with rg-58 to save weight. That can be rolled up and
thrown into a pack no problem.
Of course, you would need some trees to throw
it over, or string it between...Myself, I'd be avoiding
verticals running portable QRP...You don't have time to
lay out radials, etc, to avoid ground losses...
For VHF/UHF, hummm, maybe some kind of roll up dual
band J pole or something...??? It's hard to say,
without knowing what level of "portable" you will be...
IE: my level of portable is sitting in/beside a truck,
with the various available facilities I have with it...
IE: I have drive on mast ramps,masts, etc, etc...
I can put up a VHF GP at 20 ft, piece of cake...
If you are packing it, you won't have all that...
I'd keep it simple and low loss being you are QRP...
MK

The microwave works with RF to heat the 'food'. If an object absorbs
RF, it does so as heat, therefore, if you subject it to intense RF by
using a microwave oven, it will heat up. If it heats up, it is
affecting the antenna's radiation.

Depending on how it is connected to the antenna and type of antenna,
it may not make a noticeable difference on the signal, but in many
cases, especially where the wire is running along with or inside of a
material such as PVC, the material may have a detrimental impact on
the signal or SWR.

Not being aware of this a long time ago, I built a two meter half-wave
vertical dipole by dropping a line of wire into a piece of CPVC and
capping it off. My mobile 5/8 wave whip on the car, twelve feet below
it, using the same rig has much much better reception and signal than
the dipole. I plan to replace that antenna with a similar dipole using
1/2 inch copper tubing.

When I nuke the cpvc for one minute, it gets warm to the touch. I
don't expect to melt it using my 706, but I do have a couple of
repeaters I can't hear from that antenna that I would like to reach.

Hamsticks have a nasty characteristic. A 75m Hamstick is
self-resonant before it gets to 40m. A 40m Hamstick is
self-resonant (~9 MHz) before it gets to 30m. Self-resonance
is the frequency at which the inductive reactance equals the
stray capacitive reactance and results in heavy losses. I
don't know the self-resonant frequency for a 30m Hamstick
but I'll bet it's lower than 14 MHz. ....

Yea, you never want to use a low band stick, for upper
bands...Those sticks *must* have a decent stinger whip
to do any good. No capacitance, no worky....
But using a upper band stick on lower bands, by adding
more stinger works great. The antenna gets better and
better, as you drop bands, and add stinger length...
IE: a 10m stick tuned to 20m, by adding 2 more ft of
stinger works very well. Better on 20, than 10, if the
stinger on 10m, is a short stub..
Ditto for 20 to 40, etc...
When I ran a 6 ft 20m stick on 40m, using a 5 ft
stinger, that antenna was nearly as good as the
average bugcatcher. No joke. It kicked butt...
But that stick had the coil windings at the top, and
not evenly wound over the whole height, so current
distribution was real good. Much like a lumped coil
antenna. Just a thinner coil....MK

Dear Roy,
Perhaps that is not the objective, Roy - maybe the rationale' is
simply to decide whether or not a particular sample of material is a
"high loss" dielectric or not.

[.. 1/4 wave and 1/2 wave ...]

An antenna looks like an LC tuned circuit loaded by the radiation resistance. Your output stage has some impedance that correctly matches to it (there are exceptions we will ignore) and it is this impedance you want the antenna system to have. When the correct matching is done, the antenna works as an impedance mathcing network that matches the output stages impedance to the radiation resistance.

The normal (90 degrees to) 1/4 wave whip over a ground plane is one half of a dipole that is 1/2 wave length. The ground plane operates like a mirror. The electrostatic lines of force follow the same path with the mirroring as they would if the other 1/2 of the dipole was there. This lets you use a smaller (1/4 wave) antenna to get the same effect as the 1/2 wave.

In your case, you are not using a whip antenna. If I've read what you wrote correctly, the antenna spends more of its length parallel to the surface of the PCB than it does running 90 degrees away from it. You have some circuit with a ground plane and a limitted sized box to work with, so the mechanical shape is constained by the box and not the ideal electronics.

Since the box is small: If you have the equipment to do so, I suggest you measure (estimate) the impedance of the longest single loop of wire that will fit within the case. ie: connect to both ends. You have to have the electronics PCB in the case when you do this. If you are very lucky, its impedance will not be too hard to match to the output stage.

You aren't familiar with the FT-817? Only the neatest little 5
watt rig to ever come out. That is MY opinion of course. All mode 160 thru
70 CM, I have had more fun with this rig than any others I have ever owned.

What you are looking for is called a "transfer switch". You may want
to look for a surplus one. Transco made such a thing, both as relays
and as motor-driven switches.

None of these will be found with SO-239's tho.

Bill:

Some many years ago I needed such a switch for some experiments on 2 meters. Since it was the weekend and I was in a
hurry, I took one of the old A. H. & H. DPDT toggle switches, some bus wire and 4 N connectors and made one with leads
as short as I could make them. It is still in use, and makes a surprisingly small impedance bump in the line. I
suspect at HF, it would be invisible.

That will work. If you are running high power, you may also want to consider
a wide spaced rotary wafer switch.

Roy allow me to be a bit more directive regarding my pursuit.
I am trying to see what methods that can be used for maximum gain.
Having made many a long boom yagi 80 feet and 13 elements I have
come to the cinclusion that thinking must move away from Yagi's.
If one starts with a balloon squeezed in the center we get the figure 8
pattern.
I think we all can agree on that
My logic is that we must find a way to move all the volume at the rear to
the front thus increasing
the front diameter before we begin to massage it. The present thinking is
one sqeeze at the rear
is the best that one can do. It is here that I part company with the norm.
If we move all the volume to the front then talk of gain/boom length becomes
moot.
There are other points that I am not happy with regarding antennas in that
if we have reprocity
how is it that radio rays can arrive at angles as low as 3 degrees?
Deflection of radio waves jump right out at you
I model quite a bit but models tend to follow the input thinking so I
intentially put Yagis aside and mainly revolve around close coupling and
clustering of elements
but at the same time I am interested in what
aproaches have been made with the yagi in removing the rear volume as it
were.
I am aware that antennas have been studied to death over the years but it is
my belief
that all these studies started around yagi phillosophy which made them all
interdependent.
I believe I have arrived at a turning point in my quest and should know in a
few days
when the weather has cleared up.and I can get on the air for trials.
There we have it , no deviation from antennas just one hams thinking

who is loathe to follow others.
Regards
Art

I think that`s it. The properties of dielectrics are functions of temperature and frequency. My CRC Handbook of Chemistry and Physics shows PVC`s dielectric constant is definitely a function of frequency, unlike polystyrene and some other pastics.

I`ve seen PVC used as a base insulator for vertical elements of a HF antenna array, and it worked OK.

I think low power factor and dissipation are desirable for an insulator. My 1987 edition of the ARRL Handbook has a table 47 on pages 35-36 and 35-37 titled "Properties of Common Thermoplastics. Maybe later editions have expanded tables.

I am in Augusta. There is also an HFPack and HFNow reflector that is
for discussing backpacking and QRP or telling each other when someone
is on the air and where. Every once in a while I find a frequency and
send a message to HFNow to say I am there and try to make qsos. You
don't have to be QRP or backpack, but the QRP ops love to try to make
contact when someone announces when and where they are. They know
someone is listening for them.

i haven't been very successful just calling CQ HFPack QRP from those
frequencies unless I announce it first. But there are is a fine group
of people from around the world that love QRP.

Go to Yahoo Groups and search for HFPack, HFNow, and QRP. I am
subscribed to several of them.

72 for now.

(72 is a little less than 73, just as a QRP is a little less power) :)

No, that's not correct. If you heat up an object in the microwave oven, it indicates that an object of that material, size, and shape absorbs some fraction (how large a fraction, you have no idea) of energy when an intense microwave field is applied. It says nothing about what that object will do when put at the end of an HF antenna, where it isn't exposed to an intense microwave field.

Why yes, it might, or it might not. This can be said of any material.

That's an interesting anecdode, but it hardly supports the contention that there's a direct correlation between heating in a microwave oven

and detraction of performance of an HF antenna when used as an end insulator.

Is a material that is "high loss" at microwave frequencies always "high loss" at HF? How "high" does the loss have to be in order to detract from an HF antenna's performance when used as an end insulator? When you put an object in the microwave oven for a minute with a glass of water and the temperature rises 10 degrees C, how "high" is the loss? How "high" is the loss at HF?

This sounds like a place for the horn antenna similar to what we use
in microwave communications.

You have an interesting approach.

I am sure you have considered this, but how well do the multiple
reflectors work with the yagi? not so much those in line with the
elements as those that form a wall behind the driven element or the
first reflector.

> Or when modeled anyway....
>. . .

What modeling program are you using that gives those results? A half wave vertical over perfect ground has about 5.15 dBi gain at the horizon. The gain when mounted over real ground has zero dBi gain at the horizon, and much less than 5.15 dBi at any elevation angle above that, with the value depending on the qualit of ground.

>. . .

> If a single half wave shows 2.15 dbi, I wonder how adding
> a second element can add another 3.85 db gain...???
>. . .

A two element array can have more or less than 3 dB gain relative to a single element by means of mutual coupling. The theoretical limit is 6 dB, which would require impossibly low loss and narrow bandwidth, but 4 or 5 is readily achievable in practice. An increase of much over 3 dB does require attention to losses and nearly always results in a pretty narrowbanded antenna. In general, the mutual coupling between collinear elements doesn't favor high gain, and most collinears have gain increase of less than 3 dB for a second element. You can learn more about this topic in Chapter 8 of the _ARRL Antenna Book_.

Nug wrote:
"I am building an rf transmitter for a short range data link at 433 MHz and am almost done, but I would like to understand better exactly what I am seeing with regard to antenna performance."

Your wavelength is about 0.69 meter or about 2.3 feet. In antennas everything depends on wavelength. If you use a transmitter housing as the ground plane for your antenna, it needs to be a sizeable part of a wavelength or the salient part of your antenna must be longer to compensate for the small ground plane.

If you had an infinite ground plane, a 1/2-wave wire perpendicular to it would produce up to 50% more volts per meter field strength than a 1/4-wave wire perpendicular to the ground plane. It`s not something for nothing. Total radiation is the same in both cases. More of the radiation is perpendicular to the wire in the 1/2-wave and less goes off at some other angle to the wire.

50% more field in some particular direction is realy not very significant in most cases, and there are other consequences of using a 1/2-wave wire instead of a 1/4-wave wire.

An end-driven 1/2-wave wire presents a very high impedance. It is equivalent to a parallel-resonant circuit. It would match a direct connection to a parallel resonant tank circuit perhaps.

An end-driven 1/4-wave wire presents a very low impedance when worked against a ground plane, maybe about 30 ohms.

How well you are able to radiate a signal from a wire is likely to depend on how well it is matched to the transmitter and less about the bends in the wire. In any case the complete antenna must be resonant to eliminate reactance which opposes the signal`s entry into the wire.

For a small transmitter operating at a very short wavelength, the size of the antenna is not onerous and it would be possible to use a center-fed 1/2-wave antenna. Each half would be just a little over a half foot in length. Drivepoint impedance is in the 70-ohm range. Another possibility is a full-wave loop, about 2.3 feet in perimeter with a drivepoint impedance of about 120 ohms.

Performance of all the suggestions is probably about the same. You can find the best by trying them.

Best regards, Richard Harrison, KB5WZI

The idea of 'reflectors' is perhaps the wrong approach, I prefer the term deflectors
as one sees when rays hit a knife edge. Also close coupling enables elements to
be current heavy and others voltage heavy such that it would appear that a element was doing nothing when in fact it is the link for more current loaded elements
in cluster form. A wall that you suggest can indeed reflect and absorb radio waves but a
wall is beyond my means thus resonance remains a important function of change.
But then close coupling of elements together with the deflection aproach has been
dissed many times over the years with me and always ends in derision of the author
Time will tell but experimentation can be enjoyable especially when a trail of past results
suggests that my rubicon is at hand and close to submission to RADCOM where experimentation is still valued.

Heh, no politics here or religeon so all can join in without fear especially those who are willing
to consider and pursue 'outside of the box' ideas that others distain., in order to gain better
understanding

If you look at current flow in a corner reflector antenna you will note
that rear elements individually carry little current! Food for thought

Art

Excuse me if I misunderstand your post above. It reads to me that you
have an interest in building an antenna that minimizes "side lobes" to the
rear of the main beam.
In my experience with directional antennas I have not been able to
corelate minimum side lobes with maximum gain.
I'd suggest that the sidelobes will probably never be held lower than the
same level as the forward gain. That is a 20 db gain antenna will have
side lobes no lower than - 20 db with respect to the main lobe. Or, another
way to put it is; there will always be a side lobe that gets up to or above
isotropic level somewhere in the pattern.

I think I'm misreading your post because I read it to say that main lobe
could be increased in width while increasing the antenna sensitivity. That
doesnt make sense, so I guess I'm not understanding.

And, I submit that, with yagis, there is so little energy radiated in the
sidelobes of a 15 db gain Yagi antenna that *all* the sidelobe radiation

redirrected to be included in the main lobe wont add significantly to the Practical Useability of the antenna. I write Practical Useability because I want to distinguish that from scientific exploration of antenna gain, which accounts for fractions of one db.

Jerry

Source record: 81637

I was using elnec in that example. But I was using "free space".
I was trying to leave the ground out of it...
Also those models were all elevated at 40 ft at the base.
At that height using real ground/average, it had about 3.8 dbi
at 8 degrees.
In comparison, the 1/4 GP with sloping radials did about 1.8 dbi
free space. Real ground at 40ft, was about 3.0 dbi at 9 degrees.
So about .8 db difference using real ground.

The main reason I was sort of skeptical about the 3.85 db
increase was due to your next to the last statement.
I didn't think the close spacing would give that much gain.
As I quick test, I just tried adding another element above
the original, in that model. I used 2 sources to feed.
With the very close spacing of the two elements, the free
space gain was 3.59 dbi...A tad less than I expected...
The real ground numbers were 5.53 dbi, at 7 degrees.
So almost a perfect 2 db increase in that model over
real ground. As a comparison, with about a 1/2 wave
spacing, I got 7.23 dbi using the same real ground.
About 3.4 db increase...Could probably get more
with a wider spacing...
It's this spacing thing that made me dubious...
I couldn't see 3.85 extra, being the elements were
very close using the stub.

BTW...all the models I had were for 10m, at 40 ft....

> rear of the main beam.

Correct..minimise or remove
.
> In my experience with directional antennas I have not been able to
> corelate minimum side lobes with maximum gain.

Oh I fully agree with that observation and that is another part of my
thinking
as it should never be so UNLESS you are captive to Yagi thinking.

> I'd suggest that the sidelobes will probably never be held lower than the
> same level as the forward gain. That is a 20 db gain antenna will have
> side lobes no lower than - 20 db with respect to the main lobe.

20 db gain would not be rotatable at HF which represents a huge drawback,
better to stay with a rombic thinking and cancel the energy complely to the
rear of the
feed point.

Again that is true if you are captive to the Yagi
Make no mistake the Yagi is as about as simple a thing to make that works
well,
it is doubtfull with respect to simplicity it can be beat.

Or, another
> way to put it is; there will always be a side lobe that gets up to or
> above isotropic level somewhere in the pattern.

Then think what actualy generates a lobe whether directional(frontal)
or at the rear.

>
> I think I'm misreading your post because I read it to say that main lobe
> could be increased in width while increasing the antenna sensitivity.
> That doesnt make sense, so I guess I'm not understanding.

Yes you misunderstood. Bank to the ballon if all the volume to the rear
of the figure 8 ahat the new diameternd placed in the front of the feed
point it is obvious will be wider and with more gain and if I might adde NO
sidelob.
You have to return to basics to understand that it is energy to the rear
that
generates side lobes at the rear.

>
> And, I submit that, with yagis, there is so little energy radiated in the
> sidelobes of a 15 db gain Yagi antenna that *all* the sidelobe radiation
> redirrected to be included in the main lobe wont add significantly to the
> Practical Useability of the antenna. I write Practical Useability
> because I want to distinguish that from scientific exploration of antenna
> gain, which accounts for fractions of one db.

Well that is the essence of my disagreement with the masses which I admit
I have not yet released my findings. Think about it, I could have a single
directive lobe
that has twice the energy of a standard dipole in unidirectional form
and with a broader lobe.and I have yet to discuss yagi type manipulations
that
narrow the lobe ,which can be unhelpful, and start from a new datum line if
one
wants to determine gain per unit length type thinking that goes with
Yagi,s.
.Maybe some experts can add some view points, after all it is a general
discussion group on antennas where many believe all is already known

and in a book..... grin

It probably doesn't. I had just heard it was a way
to tell if the PVC had some kind of metal particals,
or whatever. I'm not that much up on PVC, but the rumor
I had heard was the "grey" PVC was better for HF rf use
compared to the white stuff. But I don't really know.
I've tried both, and never had any problems. The loading
coil on my shorter mobile antenna is wound on grey PVC,
and so far, I've never noticed any adverse effects.
My 2nd antenna uses a thin plastic tube, about like what
you would see on a sidewalk blower, or whatever...
Never noticed any problems with it either. I seem to have
about the same performance as an open frame coil, as far
as I can tell, and I've never noticed any heating, or
melting, etc..
My comment was more to protect the microwave, rather
than endorse the value of PVC nuking...:/ I have
tried it though...The grey stuff does stay cold when
nuked...Whatever thats worth..I didn't try the white
though...I've never had trouble with any material as far
as end insulators...I've run legal limit through plastic
coathangar insulators 3 inches long, and didn't arc...
That I could tell anyway...Same for PVC or wood...
The only time I've ever arced, was when the bare wire was
actually rubbing a tree branch...I started to burn it
up...Probably had been that way 2 weeks before I noticed
it..

I have modeled a 30 meter dipole, a Delta loop and a Quad loop (the loops 'hung' in a vertical plane). I have also spent hours reading various posts and web articles on the 2 loop antennas. I am trying to better my situation on 30 meters, my favorite band. Currently I have a dipole at about 38 feet, which is as high as I can go with the top wire and the trees that I use are no more than 48 feet apart (the dipole fits comfortably). I also have a wire vertical with 16 radials which gets dismantled when grass cutting season starts, it probably will go back up next fall. According to EZNEC, the Quad loop is a little better than the Delta loop which is a bit better than the dipole, but not by much. I did try a half square, and it seemed to work well on transmit, but it was as noisy as the vertical on receive. The dipole is nice and quite on receive, as it should be. The HS lasted 3 days before the dipole went back up.
I've never used either loop but I did at one time use the inverted L loop. It worked OK, but was also noisy on receive and I probably lost an S unit due to low gain. The dipole seems to be the best antenna I've tried under my circumstances so far, but I sure would like some opinions on the 2 mentioned loops: Is either noticeable better than a dipole? Which one and why? Are both nosier (important) than a dipole (both vertical hung,bottom fed apex down on the Delta loop and the Quad loop fed in the center of the bottom wire)? Should I just stick with the dipole and spend my efforts elsewhere? With the 48 feet between trees and my maximum height of 38 feet, is there anything better I could try?
I KNOW what the modeling programs say, but I don't always believe them and I am looking for PRACTICAL experience and personal opinions on the above 3 antennas. As it sits, I'm inclined to let well enough alone and stick with the simple dipole, unless I can be convinced otherwise.

Thanks...

You obviously understand antenna patterns, I have a little professional
experience with antenna design. But, I am an old guy who wouldnt even
qualify as an antenna engineer by today's standards. So, I have very litle
to add to your threories on antenna pattern shaping.
I would suggest to you that all antena pattern terminology uses the
pattern width to identify gain (or dirrectivity). So, to be consistant,
higher gain antenna patterns will produce a narrower main beam angle.
Again, I dont suspect that you dispute the validity of my statement on
pattern width. I do suspect I am (again) misunderstanding.

Maybe not so strange. Today we might recognize that
halo as a plastic helmet and those wings as oxygen
tanks (thus avoiding our germ-filled environment).
Everything that was reported in the Bible is possible
today except maybe for the raising of the dead but
CPR on individuals drowned in cold water comes close.

Roy, we know you are into quantitative stuff but some
of us are into qualitative stuff. We know not to put
our hands into a flame even though we have no idea what
is the temperature of the flame or what temperature our
hands reach when put into a flame. If the exact temperature
of a flame Vs a blister on your skin is important to you,
why not experiment and report? :-)

Install a center pole that keeps the angle between the
wires more than 90 degrees and keeps the ends at 38 ft.

The microwave test was written up in Hints & Kinks, 13th edition, page
6-6, although no scientific explanation was given as to why warmed
plastic would be worse than cool, after 2-3 minutes nuking on "high"
with a cup of water also present. (Author was E.R. Berg, KZ9Y.)

Jim,

If you want to mess with EZNEC some more, try feeding the quad loop at one
corner. Also at the top center. I have a sort of quad loop, actually a
trapazoid, hung vertically for 75 meters. My two 90 foot tree,

unfortunately, are only about 65 feet apart. So, to get all that wire up there the bottom horizontal wire is longer than the top horizontal wire. I am feeding it in one corner, per EZNEC calculations, with the center conductor of the RG11 going to the vertical wire. This gives a combination of vertical and horizontal polarization. Works quite well.

Haven't tried a delta loop, but seems to me you might want it upside down, with the horizontal wire as high as possible. Feed the bottom apex. If I sound contradictory, it is because I put up what fit, not what I wanted.

Jim,

I run a 40m inverted Delta Loop QRP and have worked (from
Annapolis, MD) most of Europe, several South American Countries,
a couple in the Middle East and all of the US (except Hawaii).
I use it on 40m, 30, 20m (probably best performance) 15m and
12m.... sometimes on 80m it will work "ok". I got N Carolina
on 80m one time.

The top of the loop is (roughly) 25-30 Feet up with the bottom
of the triangle only about 8 feet off the ground. That's one of the
big advantages of the DL over a dipole, i.e., height above ground
isn't as big a deal.

Short answer... I love it.

good luck
rob
n3hu

I am in the process of trying to gain a better understanding of amateur radio antennas and transmission line issues.

I am mulling-over the issues associated with driving a dipole. Let's say I have a (resonant) dipole close to ground, but perfectly symmetrical. If I were to drive the dipole from a grounded radio transmitter through some length of coaxial cable, I would expect that the drive voltages at the driving point of each wire (measured with respect to ground) would be far from equal and opposite. As a result, I would expect that some current would need to return to the ground terminal at the transmitter through some means other than the inner surface of the coax shield. This spurious current could return on the outside of the shield and/or through the ground itself, leading to line radfiation and/or power loss. Of course, I would not expect a ladder line to solve the basic problem.

So, it would seem that driving a dipole directly with coax is not the best way to do things. Is that correct?

I suppose one needs a so-called "current balun" to ensure that the antenna currents are equal and opposite, avoiding a spurious return current. My simplistic way of understanding why all of the return current flows along the inside of the braid is that the outside of the braid is shielded from the center conductor, resulting in a huge outer-braid loop inductance. And current takes the path of least impedance, which is the low-inductance loop formed by the center conductor and inner-braid.

That's it for now. Any comments will be appreciated.

Small transmitting loops can work fairly well above a few MHz, but they are expensive to make. They need very low loss (because the radiation resistance is almost nil) and a very high-voltage (10's of kV) motor-driven capacitor arrangement. You can easily buy them commercially covering 10 MHz - 30 MHz. They are an option if you don't have space for a large antenna, don't mind shelling-out $380+ bucks, and don't mind re-tuning whenever you change operating frequency.

I understand the H-fields are huge close-in, so one needs to be careful.

I don't think you can beat the Buddipole with the 817. I have been using one in various configurations for a couple of years now and have had more fun with it than any other antenna. I often use a random length wire with the ZM-2 mini ATU as well, which is great if you need a light weight set up.

I often use half the buddipole mounted on the car as a vertical with my Yaesu FT-857 and 100W. It is far more efficient than a short mobile whip but obviously it can't be used when mobile. The Buddipole can be used on 80m if both coils are used with both arms as a vertical whip with an earth or radials.

I can deffinately recommend the ATAS-120, I use one with my 857 and am very impressed. Have a look at the reviews on www.eham.net as it should help you make your mind up. The ATAS is not the biggest screwdriver antenna around but it does work, even on 40m. I have no problems working all around Europe from the south coast of England on 40m. It is more efficient on the higher bands like all mobile antennas, but like you I love the convenience of quick band changes. I am able to work all that I hear on mine, I worked VK on Saturday morning on it with a 5/9 report on 20m.

Correction -- a *quarter* wavelength ground-mounted vertical has the gain I quoted. A half wavelength ground-mounted vertical has a slightly narrower pattern, resulting in a little more gain over perfect ground. It's about 6.9 dBi at the horizon.

If you can find the publications, I recommend that you read "Some Aspects of the Balun Problem" by Walt Maxwell, W2DU, in March 1983 QST, and "Baluns: What They Do and How They Do It" in the ARRL Antenna Compendium, Vol. 1.

Do you have any suggestions for my locating Walter Maxwell's publication
on baluns? Also, where can I buy the ARRL Antenna Compendium Vol. 1?
I'll go to Google right now to try to locate the ARRL publication on
antennas.

Maxwell's home page is at http://home.iag.net/~w2du/ where you'll find
his article on baluns.

For the Antenna Compendium(s), go to www.arrl.org and then to their
bookstore where all of their antenna books are for sale.

2820. dipole extension?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-22 02:01:45 UTC
From: ml <m@di.net>
Message-ID: <m-946F79.21014121022005@news.verizon.net>
Source record: 81659

Hoping someone might have a idea as to what's best in this situation...

My set up

a sgc237 tuner at bottom of a (center support) 5' pvc mast, feeding 5' 450ohm ladder line to a horizontal center fd dipole

Issue:
unfortunately i don 't have too much horizantal roof space seems i'll have about 40ft on one side maybe 20ft on the other

the ends will be supported by tv mast and clamped onto the sewer (cast iron?) vent pipe on each far end

The far end masts are 10ft tall (making entire dipole 20ft off roof surface)

3 questions:

a) would it be better just to leave the dipole as is horizonal(and kinda short for multiband dreams) or

b) extend it by adding a 10ft verticle wire along the mast (using plastic spacers?)drooping down

c)attach my dipole to the mast making it part of the dipole (this presumes the cast iron sewer pipe makes too poor a connection to matter i don't know , suppose i can rap it w/duct tape)

2821. Re: Does a 5/8 wave antenna need a metal ground plane?

bbnn wrote:
"I know that a 1/4 antenna needs one to work but do the 1/2 and 5/8 ant need a metal ground plane?"

A radio has a pair of RF signal connections. It isn`t the length of the antenna which determines the need for a counterpoise. Balanced antennas have a pair of connectors. These are interchangeable and may be connected to the radio`s pair of RF connections. If the transmission line wires are close-spaced, they don`t tend to radiate much.

An unbalanced antenna works against the earth, a ground plane, or a counterpoise. It may have only one insulated connector. But the radio requires two RF connections to make a complete circuit. The unbalanced antenna needs a connection between the grounded side of the radio, or one of the ungrounded RF terminals if there is no grounded terminal, and the side of the antenna meant for a ground connection, such as its ground-plane. This connection frequently is made by a coax`s external shield.

If you have an unbalanced antenna, it needs something like a ground plane so that you have something to connect the grounded side of your radio to for a complete circuit. Otherwise the transmission line becomes part of your radiator.

A balanced antenna, such as a dipole or a loop, has interchangeable terminals and needs no connection to the earth for a complete RF signal path. A ground plane would be superfluous.

Best regards, Richard Harrison, KB5WZI

Recall from previous replies that:

1. Cast iron roof vents are supported by and grounded to building structural steel. They will probably not be a good choice to terminate an antenna right next to. Then again you could be improving SWL reception in all the lavatories of the building ;-)

2. The building's t.v. antenna (and thus tenant's televisions) is may be a pretty good receiver for anything you transmit right next to it. Using the t.v. mast as part of your antenna? I would stay as far away from it as possible.

Why don't you consider one of those toaster-oven (Isotrons?)? At your high elevation they probably work as well a their design ever allows. For at least 23 hams who made the reviews on eHam, the things do work at least marginally well, and take up practically no space at all. Just my 2 cents, since a dipole seems such a challenge for your conditions.

thanks for the responce

by tv mast i ment tv style 1 1/4" pipe not the actual mast with the
building antenna

the isotron was a interesting idea but a dipole is what i will have to
surfice with it's not much of a challange, but some of the 'details'
are a bit more difficult than thought

i do hope someone will be able o answer the questions i posted (other
than your reply to "c" being n/g)

tnx

--- on the heady topic of "Re: F to B and F to rear"

How about stuffing a dielectric type material between the elements so
that the antenna can be made a lot shorter though it still remains
electrically resonnant? How about making antennas 3 dimensional
instead of on a single plane? How about using newly discovered
materials exploiting their strange new properties.?

I don't mean to upset any apple carts but this stuff has been done for
almost 200 years and no really new ideas have been introduced since
the past half century.

HI Dan,

If you're satisfied with the performance that's all that counts.

As I mentioned, I tried one as my first antenna and really didn't have anything to compare it to until I changed and everything else I tried did a better job for me. One night I mentioned this on a repeater that stretches a couple of hundred miles and several others related their experiences and like I said, I never heard anything positive about that model until on here.

But like I said, if you're satisfied, great! My main point in commenting on the antenna in the first place was in case you hadn't tried other antennas like I hadn't when I bought mine.

2828. Re: 1/4 vs 1/2 wavelength antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-22 06:43:53 UTC
From: yahdjt@bigfoot.com
Message-ID: <1109054633.512648.13970@l41g2000cwc.googlegroups.com>
Source record: 81666

Thanks for all your responses, good stuff here.

Rich, I am using TX modules from Liapac which specify a 50 ohm load.

So putting it all together (I think) by bending the antenna (both 1/4 and 1/2) I am messing with its impedance and subsequent matching? So I would be better off with a straight 1/4 over ground plane if I had the choice.

>From reading I've done I think that a bend from vertical to horizontal (closer to ground) would be decreasing the antenna impedance, does that sound correct? Would I benefit from adjusting (extending) the antenna length slightly (I don't think so because it would no longer be at wavelength, but I am not sure?).

Ken said ... "If I've read what you wrote correctly, the antenna spends more of its length parallel to the surface of the PCB than it does running 90 degrees away from it"... Actually it's about half and half (feed> up 15mm , loop around the case, up - {clear of case} 130mm). Note the horizontal loop does not cross over itself.

Sort of like this (~~ is horizontal loop) side view.

```
|
|
|
~~~~
|
feed
```

I understand that more of the radiation is perpendicular to the wire in the 1/2-wave (than 1/4 wave), broadly speaking how will the bend('s) in the aerial effect radiation pattern (I understand this is tough to answer)? I can't fit a full loop inside the case.

I have no rf test equipment so can only use trial and error, thanks again to all who responded. As I said it actually works fine it's just I don't like not understanding the reason its working, and would like to make any small changes that may improve performance.

Thanks Again

Jim,

I have also tried several horizontal and vertical combinations (everything you mentioned except a quad loop) on 30 meters. After lots of very unscientific experimentation and observation, I ended up with: A multi-band vertical (Hy-gain AV-640) which I use as my 'reference' antenna, and a horizontal delta loop at about 40 feet. I find the delta loop quieter than a previous dipole or the AV-640 vertical; it has a flatter SWR curve (although that doesn't seem to matter much on the narrow frequency allocation on 30 meters); and gives me better DX signal reception _almost_ all the time (once in a while the vertical beats the loop, but it's rare). The delta loop's characteristic impedance is 100 ohms, and I feed it in the corner with a 1/4 wavelength of RG/6 as a matching balun. Although the calculated length of the loop should be 97.14 feet (frequ/983), I found that the best resonance occurs when the total wire length is closer to 103 feet (lesson: you can always cut it shorter, but can't cut it longer).

Larry,

You don't apply the dipole fudge factor to full size loops. In fact, some people claim it should be longer than a free space wavelength. I have seen various formulas for the length between 1000/f and 1030/f feet. I started out with 1030/f, but ended up shortening it by about 2 %. I suspect some of that depends on how close to ground you are; also, I think my wire stretched.

--- on the heady topic of "Re: F to B and F to rear"

How about stuffing a dielectric type material between the elements so
that the antenna can be made a lot shorter though it still remains
electrically resonnant? How about making antennas 3 dimensional
instead of on a single plane? How about using newly discovered
materials exploiting their strange new properties.?

I don't mean to upset any apple carts but this stuff has been done for
almost 200 years and no really new ideas have been introduced since
the past half century.

2832. Gain increase from scanner antenna to quarter-wave?

Newsgroup: rec.radio.amateur.antenna

I'm tracking a high altitude balloon on 2m via a handheld scanner, and in the past have used the standard rubber-duck antenna that the scanner came with. However, reception isn't too great at times. What kind of gain increase could I expect to see if I were to replace the current rubber-duck antenna with a quarter-wave antenna (designed for 2m and 70cm)?

Thanks in advance for any insight!
Dave

I said in the original post that I didn't always trust what modeling
programs say, but in the case of 'length' I tend to agree with what it is
projecting. I've modeled both the Delta and Quad loop over and over, and
they always come out that the best overall length is closer to 1030/f.
1003/f is always too short, at least at 35-40 feet up. Whatever it is, as
Larry pointed out, it's easier to shorten the elements than add to them.
Larry, I use my vertical as you do: a reference antenna. However there are
times when it works better than the dipole. Depends on propagation effects.
Both have a place, but I can't (too lazy) keep the vertical in the grass
cutting season :+)) .

2834. THE ULTRA ADVANCED PSYCHOTRONIC MONEY MAGNET

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-22 15:27:49 UTC
From: ormusalchemy@aol.com
Message-ID: <1109086069.160042.19330@c13g2000cwb.googlegroups.com>
Source record: 81573

Life Technology Research International®
www.lifetechnology.org
email us at: ormusalchemy@aol.com for more information

The Psychotronic Money Magnet☐ Ultra Advanced Version 1.0
The Ultimate in Causal Engineering Technology
www.lifetechnology.org/ultramoneymagnet.htm

Through the aid of spiritual guidance given to us by the higher forces we have discovered a uniquely different and improved method of creating our well known Psychotronic Money Magnet☐ .The new method was delivered to us through an exceptionally gifted channel and we were astounded by the information that we were privileged to have received. According to the information the new method which we are adopting can raise the subtle energy characteristics and the manifesting capabilities of The Ultra Advanced Psychotronic Money Magnet☐ more than one hundred fold.

According to numerous testimonials this powerful device has certainly proved that it has the power to change one's financial situation for the better in the shortest possible time, and it is without doubt the most powerful and successful money generating talisman of all time. The sole function of The Ultra Advanced Psychotronic Money Magnet☐ is simply to create opportunities for it's owner to gain money and prosper financially. The longer one possesses this unique cosmic money magnet , the stronger it will become, and the more money it will draw to it's owner.

We have been using this device ourselves for some time now and experienced a massive increase in company income and profits just a few days after the first creation of The Ultra Advanced Psychotronic Money Magnet☐ .We have been exceptionally blessed by the higher forces and in particular by the wisdom of The Archangel Mikhail.

Originally Life Technology Research International® had listed these devices as Psychotronic Generators☐ designed to be programmed for various different types of archetypal energy (trend) ,but when we became aware of the massive demand for the money and wealth programmed Psychotronic Generator☐ it was decided to being marketing The Psychotronic Money Magnet☐ as a specifically programmed stand alone device. It is only now that we have been given specific information to create a magical tool that will quite simply transform ones life.

Could The Ultra Advanced Psychotronic Money Magnet☐ become the most powerful metaphysical tool ever created? It is our belief that the most

significant difference between this device and other forms of magickal talisman or life changing catalyst (eg NLP ,Huna , Hypnosis, Kaballah , Magick etc) is its passive mode of operation, ie no conscious input is required from the user, and unlike many other talismans the device will function optimally without any necessity for a certain belief system on the part of the user. The Ultra Advanced Psychotronic Money Magnet☐ is so powerful in fact that it will override the belief system of the most hardened sceptic, and will reverse the mindset of the most pessimistic belief system.

Life Technology Research International® has taken this technology of 'Causal Engineering' and using methods based on the developmental work of Pavlita, Rifat , Fortune and many hours of Russian Psychotronics research we convert quartz crystals to Psychotronic Generators☐. They amplify, produce and direct bioplasmic energy to modify quantum mechanical collapse, changing the course of events in the macroscopic world. This device uses a multiphase set of fields which apart from altering events, inculcate a theta rhythm of around 7 to 8 Hz, the natural theta frequency of the planet being 7.82. This frequency is the Schumann Resonance, the doorway to the world of causal engineering, ie consciously creating and manifesting ones desires.

The Ultra Advanced Psychotronic Money Magnet☐ acts by establishing a new pattern of financial abundance in the subconscious and subtle energy fields of the user by harnessing the lifeforce and wealth enhancing powers of the Hebrew letters of the Kaballah. It is widely recognised in esoteric science and by academics such as James Hurtak and Stan Tenen among others that Hebrew letters through their specific mathematical structural geometry contain information that encodes life force energy, ie it provides an intelligent template for natural creative forces. It is these magical primal creative forces of The Kabbalah that we harness and focus in the preparation of The Ultra Advanced Psychotronic Money Magnet☐

In the 1920's it was discovered that quartz crystals resonate at 32,768 khz. Seeing that the Great Pyramid of Khufu or Cheops Pyramid, is made mostly of limestone, which stone crystal matrix is mostly quartz, It is proposed that the entire pyramid operates as a conciously programmable cosmic biocomputer or radionics device, a massive Psychotronic Generator☐ originally capable of harnessing and directing the focussed intent of the Egyptian priests who were its engineers .

The fact is that everything in the universe vibrates and oscillates. Therefore the connecting link between all forms of energy is vibration, sympathetic harmony and resonance. By studying and applying the principles of vibration we are enabled to see beyond material matter and into the primary creative forces of nature. Utilising the information from diverse fields such as Radionics, Psionics ,Psychotronics ,Quantum Physics ,Sacred Geometry, Sonics ,music and metaphysics has led to an understanding of how the human mind can interact creatively with the material universe.

Essentially, when the biotronic matrix of The Ultra Advanced Psychotronic Money Magnet☐ interacts with the conscious will of the operator it causes subtle changes to occur in the microcosmic universe which translates to manifestation in the macrocosmic universe (real world).

This device will naturally induce a theta state in the user as it alters reality to make money, wealth, abundance and affluence etc. more probable. The Ultra Advanced Psychotronic Money Magnet☐ is charged with the specific programming described above ,or may be programmed with your own specific intent. On request, Life Technology Research International® creates Psychotronic Generators☐ to generate any operational trend field which will facilitate the materialisation of any wish.

The Ultra Advanced Psychotronic Money Magnet☐ may be used in each of the following ways:
Place on a desk or on a bedside table for passive functionality, no input from the user is required.The device is an ideal size to be carried in a pocket or kept in a handbag. It is better that the device should be kept as close as possible to the user, ideally within 2 meters.

The device may also be kept under a pillow while sleeping where archetypal information will permeate and influence the subconscious mind ,or held in the hands or placed on the body while meditating. While relaxing or meditating it is an excellent idea to hold the crystal in either or both hands and focus positively on areas of ones life where positive financial change could occur, ie ones job ,business practices ,salary level etc. Create a mental movie and visualise achieving a wealthy ,prosperous state of existence. In any form of conscious subtle energy manipulation, results will occur through the artificial enhancement of natural processes. It is therefore important to recognise the new opportunities that you will attract to your life which will direct you towards a new paradigm of wealth and prosperity.

Ordering
The Ultra Advanced Psychotronic Money Magnet☐ supplied is the highest grade clear rock quartz . Please note that this is the much more powerful version of our other Psychotronic Money Magnet☐ for sale at our site and other auctions for $90. Each Ultra Advanced Psychotronic Money Magnet☐ comes with instructions for use. Each individually created Ultra Advanced Psychotronic Money Magnet☐ is priced at $180 US dollars. International shipping is priced at $10 US Dollars.
Shipping Insurance is optional.

Our 100% customer satisfaction rating at ebay indicates how pleased our customers have been since we began supplying our metaphysical products there. Please visit The Life Technology Ebay Store at http://stores.ebay.com/life-technology

This product may be of interest to students or practitioners of Alchemy ,Kabbalah, Reiki, Homeopathy, Healing, Buddhism, Shamanism, Pagansism, Rife Therapy, Chakra Therapy, Witchcraft, Antropology, Wicca, Magick, Huna, Hypnosis, Nlp, Rosicrucianism, Mysticism, Radionics, Psionics and Psychotronics etc.

2835. Re: Gain increase from scanner antenna to quarter-wave?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-22 17:39:19 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cvfqo7qsp1@titan.btinternet.com>
Source record: 81574
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.misc

Dave,

The thing to remember at VHF is that the dimensions of the hand-held transmitter/receiver box are just as important as the dimensions of the antenna.

For example, a properly-designed hand-held transceiver plus a rubber-duck, isolated from ground, is equivalent, in overall length, to a half-wave dipole.

Likewise, a vertical whip mounted on a vehicle behaves as a halfwave antenna of length crudely equal to whip length + vehicle depth. (As modified by a loading coil if any.)

If the rubber-duck (which is mostly a helical loading coil) is replaced by a rod or wire of longer length, two things happen -

First, the resonant frequency of the system (antenna + box) changes.

Secondly, the antenna pure input resistance changes from its optimum (designed for) value to an entirely different impedance of resistance + reactance.

In your case, due to its longer length, the antenna + its new smaller loading coil (if you fit one) will certainly radiate more efficiently. But the mismatched transmitter power amplifier (which you havn't got) will now be appreciably less efficient.

With the rubber-duck the antenna will be matched to the receiver input. But with a different antenna impedance there will be a considerable mismatch loss and receiver sensitivity will also be reduced.

Ideally, if the antenna is changed then both Tx and Rx impedance matching arrangements should be changed. Which you can't do!

So the BEST you can do is change the antenna rod or wire length such that the overall length of the system (antenna + box) is crudely 1/2-wavelength at the working frequency and HOPE that you gain more on the swings than you lose on the roundabouts.

You will likely be more successful on receive than on transmit. But it is quite possible for performance, especially on transmit, to be worse.

The most likely result is that you will hardly notice any difference. At best, if you could measure it, you can expect a few dB improvement. Depends on how big is the rubber-duck you begin with. Don't throw it away. You may wish you hadn't.

Another thing to remember is that the extremely uncertain hand and arm which holds the scanner forms an integral part of the radiating/receiving system. A sweaty palm and an arm held over your head can seriously affect tuning.

Orientation (polarisation) of the antenna relative to balloon antenna orientation can also make a great difference.

Exact length of antenna (resonance) is a very non-critical matter. Just connect some wire to the antenna socket and be prepared to prune it.

What does your "Reception is not too great at times" mean. To effect a noticeable improvement, a 4-times increase in power from the balloon transmitter would be noticeable. (A 4-times increase in power is equivalent to twice the height or distance.)

Great fun is available just from all the uncertainty involved.

Happy experimenting!

Reg, G4FGQ

Similar to Asimov, I believe that the laws of physics are pretty much known about antennas and therefore not much new will come from that, however, I don't necessarily believe every antenna design has been found. I believe that there is plenty of room for improvement on antennas for frequency Z when one only has X by Y space.

I don't believe that the laws of physics will allow an antenna design that is more efficient (in terms of material, space and wind-resistance) than the Yagi. That's not to say that one can't invent a better vertical, array or some kind of gain antenna for a restricted area. I always believe there is room for improvement.

I differ with Asimov in that I would not want to discourage you from seeking out the new antenna design. You may surprise us all and find that more-effecient antenna, or you may just find a different style antenna that fits some particular purpose. Either way, we all win.

Edison was called a failure and told he was wasting his time when he didn't get a working light bulb out of hundreds of tries.

Good luck

Significant. I don't have a number, but it will definitely improve.

On the balloon, is the antenna vertically polarized? I would assume
so. If not, consider a dipole.

Also, to improve the reception further, build a 'rat-tail'. Its a 1/4
wave wire that hangs from the ground of the rig making your 1/4 wave
antenna more of a 1/2 wave. You may find adding that will help even
with the duck.

Hi Dave

Assuming you build a 1/4GP with a large enough counterpoise (ie dont rely on the case of the scanner) I think the figure of merit is around 6-12dB. You may however be better off making a turnstile about 3/8 wavelength over a mesh ground so the thing points roughly where you want it. That will also help with polarization changes as the baloon rotates. Maybe a similar antenna on the ballon as well?

Cheers Bob Vk2YQA

Reg,
Thanks for the feedback. I really appreciate it! If I could, I had a
few additional questions regarding some of your points:

The antenna I had in mind was made for Radio Shack handheld scanners,
and I have a Uniden handheld, which both have a 50 Ohm impedence I
believe... this would eliminate the impedance mismatch, wouldn't it?

> The most likely result is that you will hardly notice any difference.
At
> best, if you could measure it, you can expect a few dB improvement.
Depends
> on how big is the rubber-duck you begin with. Don't throw it away.
You may
> wish you hadn't.

The antenna it came with is about 6" long, and I assume it's made to be
a decent antenna for all frequencies the scanner is designed for (29MHz
to 900+Mhz). Just FYI, in case that changes anything...?

> Orientation (polarisation) of the antenna relative to balloon antenna
> orientation can also make a great difference.

That would be great if I could control the orientation of the
transmitting antenna. It can vary +/- 45 degrees or so during the
flight... the transmitting antenna is an inverted standard 2m handheld
antenna (8" or 9" long?). I've assumed in the past that if I held the
recieve antenna vertical, that's about as good as I can get...?

> What does your "Reception is not too great at times" mean.

On the way down mainly, when it's decending between 30 and 100 mph.
I'm assuming this is due to antenna swing.

> To effect a noticeable improvement, a 4-times increase in power from
the balloon transmitter would be noticeable.

I'd love to, but due to battery capacity and time of operation, .5W is
what I'm trying to stick with.

Thanks again for the insight! I very much appreciate it.

Dave

Really? Any point on the ground? Or does it need to be connected
somewhere on the antenna?

Thanks for the advise!

Very sensible!

Don't risk suffering from delusions of accuracy.

Modelling programs are invariably less acurate than the data stuffed into them.

And the data stuffed into them nearly always contains nonsensical elements.

Yet results are religiously quoted by old-wives as being of gospel truth and value, equivalent to misquoted, out-of-context, statements by Terman and Kraus.

Who believes antenna relative gain figures stated in milli-bels at 14 MHz, or the take-off angle is 20.7 degrees, when the DC ground conductivity is average and ground permitivity, just as important, is not even mentioned?

And a 1000 other examples.

Jim Leder wrote:
As it sits, I'm inclined to let well enough alone and stick with
> the simple dipole, unless I can be convinced otherwise.

That's probably what I would do. In most cases like that, I prefer
the dipoles over the loops...Why? Cuz in general, more of the current
will be up at that apex height, than the loop, which usually will
have to have wires dropping lower to the ground, in order to fit.
If I've got 35-40 ft of height, I prefer to keep the antenna currents
at that height. If you have a delta loop, or any other, usually the
bottom will be fairly close to the ground. More ground loss, and
in general less effective than having it all at 35-40 ft...The
small increase in broadside gain hardly seems worth it to me.
Usually, it's hardly noticable...If I wanted gain, I'd run parallel
dipoles phased, or something along those lines...
I know you don't have the room, but a simple EDZ is more effective
than a loop, as far as the broadside gain..And you can keep it
all up high...An EDZ on 30m would be about 96 ft or so total length..
Anyway, I don't think the loops would be a drastic improvement, if
much at all...But that's just my $2.31 worth...

He has been told this at least a dozen times in former posts..... in at least half a dozen news groups. He was given some very explicit directions on what to do. Failing that, he needs to send it to Alinco, since it seems all help has fallen on deaf ears or blind eyes. There is nothing wrong with asking for help, but this has reached the point of trolling.

Source record: 81587

I have a 20 meter EDZ up about 35 feet and, yes, it is a very nice antenna.
The only problem I see with it is it's apparent narrow beamwidth. But, hey,
it's broadside NE/SW so I'm OK with that. I looked at one for 30, and know
that it would be nice to have one, but It would replace the 20 meter EDZ
(only place it would fit) and would not be high enough to be too effective.
I am very strongly leaning towards letting the dipole stay and MAYBE
getting off my duff and making the vertical more permanent and improving the
radial field.
I DO appreciate the comments. I have been debating this for some time now.
What else to do in mid winter in the Ohio but to think about spring time
antenna projects.

Hi Dave,

Well, I see you got advice, but unrelated to the problem you offered.

The standard rubber duck and a quarterwave are going to have the same failings: they both have the same response curve in space. Basically they both are designed to work with transmitters located at right angles to them. And if you stand in the conventional upright manner of a biped, then those antennas are going to be vertical with the favored direction lying along the horizon.

Now, if your balloon is tracking along the curve of the earth's limb, some several hundred miles out, then this might work admirably (it doesn't take all that much power to hear this distance when nothing is in the way). However, as balloons go, they are generally above you and your antenna is pointed toward them, or nearly so (certainly more so than at the horizon). This is NOT a favored direction for communication and antennas when they are small (and a rubber duck, a quarterwave, or a halfwave easily meet that dismal prospect).

To obtain overhead coverage for communication (and this presumes that the balloon antenna is also vertical - which means it will suffer from the same geometry); then you need an antenna that is at least one wavelength long, or longer (1ï¿½ wavelength would be a nice way to go).

Long antennas have more sensitivity in the direction along their length.

Now, if your tracking pastime includes all angles from the horizon to directly above, then you need to consider designs that are more isotropic (and none of the suggestions offered by everyone, including me, come anywhere close).

Richard,
Thanks for the advise. However, I thought 1/4 wave antennas were more
isotropic than 'most' other antennas... (see link below)

http://www.astrosurf.com/lombry/Radio/dipole-height.gif

What am I missing?

Basically, all I'm trying to do is increase the sensitivity of my
handheld scanner for the 2m range.

Thanks,
Dave

Dave, I have seen you get some good information and some bad
information. The 1/4 wave will give you better results over the short
rubber duck.
There will be not much difference in the pattern between the original
antenna and the 1/4 wave. There will be an improvement in signal level
by about 10 dB. One poster said that you were in trouble because your
antenna was vertical. I am willing to bet you can turn your head and
look upward with the scanner turning upward as well.

Your radio is designed for a 50 Ohm antenna so half or more of the
information given by "Reg Edwards" is bogus as well. I don't think he
tried to mislead you, but may not have experience in real life experiments.
The case of the radio is important only in how it capacitively couples
with your hand or body.
A short vertical has an impedance far below a normal quarter wave. That
means your idea matches better to your radio.
As a sort of ground wire, a 1/4 wavelength long counterpoise, (as
someone said a rat tail) will also help.

most commonly they are connected to the bnc ground, but anywhere that
is grounded to that connector will work. Since this is a scanner, you
might consider a piece of computer ribbon cable. Cut each wire in the
ribbon to 1/4 of your favorite bands or frequencies until you run out
of wire. If you have left-over strips, just remove them or leave them
for later use.

Just a thought.

Hi Dave,

Umm, those are lobes for a HORIZONTAL dipole --- wrong polarization,
wrong size. Cross polarized signals come with beaucoup loss.

>Basically, all I'm trying to do is increase the sensitivity of my
>handheld scanner for the 2m range.

If the balloon is overhead (or off of overhead by ï¿½15ï¿½) you are 10dB
down at best, or sitting in a deep null (deaf city). To compare that
30ï¿½ cone of silence: Hold your hand directly overhead, spread out
your fingers and thumb, the distance between little finger and thumb
tips spans 13 to 15 degrees (half that cone).

Is your balloon in that cone? Worst possible place for a short
vertical antenna to hear; and for a balloon with a short vertical, you
are in the worst place for it to shout down to you. This is a deadly
combination that puts your normal signal at -20dB (or worse).

A KW linear may overcome this sensitivity problem however.

Hi, all,
I am new to RF, but (un)fortunately i am handling a transferred project on RFID. Some of the rf concepts i am not not so sure, and seek for assitance here.
Let me give a bit more on the original designs first. They are tags that talk to each other unlike the passive tag. This design is already working with a quarter wave-length antenna. My task is to modify it to a smaller (shorter) one.
The design is like :
antenna----matching circuit----transceiver----mcu

Now comes the questions:
1. when we talk about the load impedance, where should it start counting? From transceiver down left or from the matching circuit down left?
2. the original matching circuit is working for the quarter wave length antenna. Do i need to adjust the value (C and L) if i replace them with other forms of antennas(e.g chip antenna, loop antenna)?
3. How am i going to measure the load impedance? What equipment is needed?

thanks. Any advice is favorable.
Sigma

stryped,
Then I would think the logical questions to ask are;
Was the replacement battery any good?
How long ago was this replacement done?
Was the battery replaced correctly?

If the answers are that the battery really was good, and it hasn't been an unreasonable period of time since replacement, and if the battery was replaced correctly, then it would seem that there is something else wrong. If you can't find the problem, send it back to the manufacturor, let them find it.

Montoya (Sigma),

You did not give any indication of the frequency you use, and commercial RFID tags range from somewhere around 125 kHz to over 5 Ghz. Makes just a little bit of difference.

This can't be part of a legitimate commercial project or else the company would already be bankrupt for lack of adequate staffing. Assuming it is a student project the recommendation would be to contact your professors and fellow students to learn more about RF.

For some specific ideas check out some of the voluminous documentation available from RFID manufacturers. For example, Texas Instruments has a lot of RFID documents available for downloading, including a 47 page technical note on antennas for RFID. The high level site address is www.ti.com/rfid

Are there any online sources that show vertical whip antenna take-off
angles vs. antenna length (as a function of wavelength)?

I don't know about "deadly"... atleast not in this scenario. :-)

Keeping the transmitter and reciever constant, what would you recommend
for the transmitting and receiving antennas in this case?

Thanks,
Dave

If one pursues this 'out of the box' hypothesis it can be seen that the
earth itself,
because of it constituents ,will consistently emit photons all the time such
that it will dwarf the
radio waves with respect to energy containment differences as well as energy
received from
beyond earth. It there fore can be seen that the earth itself can be mapped
out with respect to
photon emmisions and without reference to shore lines, mountains,buildings
e.t.c.
This map could in fact be made up of colours depending on frequencies of
emmissions.
It could well be that birds have the ability of 'seeing' such a map that
would allow them
to uneeringly navigate the oceans or migrate without material sign posts or
allow a homing
pigeon to speedily return to home. This does have drawbacks in that the
'map' can be totally distorted
when the earth is bombarded with outside energy leaving migratory birds in a
hopeless state until
the interference abates as with sun spots and normalcy returns with respect
to the natural
emmission of earth photons.
Moral is that you do not release homing pigeons during sun spot activity.
Perhaps I shoulds resume my antenna activities or I will never get things
done..grin

Done and done... nice program! I'm hoping I entered the correct values for everything. Do the patterns listed below look correct? I assumed things like wire diameter (I used 2mm) didn't affect the output significantly... although I did notice some things like the number of segments did affect the output if I decreased them (I used 10 for these cases).

(filename = length in wavelengths):

http://www.geocities.com/achilles03/eighth.gif
http://www.geocities.com/achilles03/quarter.gif

Good question, and I'm sure you got lots of good answers. I'm sort of a beginner myself, but one way I think of radio waves is like this: it's a different kind of light. The light you see and radio waves are essentially the same thing (electromagnetic radiation), only your eye can't see radio waves. A radio antenna is like a light bulb, and different antenna shapes are like different shaped light bulbs. The main difference between the light we see and radio waves (that are transmitted) is that radio waves are created in phase from the antenna (like a laser), while the light we see kinda just streams out from whatever's creating it (ie not in phase). The fact that lasers create light in phase is why they're used for so many things, as opposed to just a really straight flashlight beam.

Hope that helps,
Dave

Hi Art,

Why do you think this is "out of the box"? Photon emission over a huge range of wavelengths is all around us.

The earth has been mapped by photon emission 'forever', in color no less. You may choose to call it photon reflection, but the end result is the same. Photons are everywhere.

I hate to get personal, but do you have working eyes? Can you feel heat from the sun?

Photons rule.

RF transmitters are not impedance matched to antennae in the sense of maximum transfer of power. "Maximum transfer of power" is a small signal (ideal linear parameters) issue, not a large signal issue. That is, the antenna/load are not conjugately matched. What is said, is that a TX'er will deliver some given power into, for example, 50 ohms. This says nothing about the output impedance of the PA.

Power amplifiers are concerned with DC input power to RF output power efficiency, thus they are load-line "matched," not impedance matched. The concept of "output impedance" breaks down for large signal devices. For example, what is the output impedance of a class C or D amp taken when the transistor is on or off? I suppose one could consider the time-averaged impedance, but I'm not sure of the utility (to be fair, the time-averaged reactive output component is tuned out as best possible). The vague output impedance is a problem even for large signal class A devices. Again, RF PA's should be load-line matched. Output-Z is irrelevent.

2865. New MFJ Telescoping Mast and Possibilities

Newsgroup: rec.radio.amateur.antenna

OK. MFJ has a 33 ft. Telescoping Fiberglass Mast and collapses to 3.8 ft. If ever there was a pole with possibilities for multi design vertical antennas and dipole/inv.Vs of the portable/toteable/permanent type, this is it. It weighs in at only 3.3 pounds and costs $80.00 See the '05 catalog page 43 full details. It is flexible, it is black making it somewhat stealthy and it is UV resistant. MFJ has done only enough math to show that fully extended it is a full 1/4 wave for 40 mtrs. I don't know how many sections there are but each one pulls out and twist locks into place. I'm going to get one and play around with it. I'm dead in the middle of restricted covenant hell. My fault for that, I had a stroke right in the middle of new home search and my wife found this home in gated community bought it, but didn't think to ask about the covenants.

Sigma wrote:
"This design os already working with a quarter wavelength antenna. My task is to modify it to a smaller (shorter) one."

An antenna shorter than resonant length uses a lossy loadong ciil(a) in most cases to neutralize its capacitive reactance. The antenna system must be resonant so that reactance does not limit energy into the antenna.

A 1/4-wave of wire is only 1/2 of an antenna. The other 1/2 of the antenna must be supplied by another 1/4-wavelength of wire or by an image-maker such as a large conducting sheet or a ground plane. The image maker is larger than a lone 1/4-wavelength of wire.

A 1/2-wavelength of wire is resonant and it is a complete antenna. A 1/4-wavelength is not.

A shorter than resonant-length of wire is less directional than a full-length antenna, but not by much.This means there is less "gain" in it at its best direction. Its real problem is its fast rising capacitive reactance as it is shortened from resonance. Another problem is its dropping radiation resistance which causes its loss to heat resistance to take a larger share of its total energy.

There is a way to slightly reduce the length of a resonant dipole, and that is to make it fat instead of thin. This is usually costly, inadequate, and inconvenient. The length of a 1/2-wavelength conductor is only 94% of a 1/2-wavelength in free-space if its diameeter is 1/1000 of a wavelength. See Fig 8 on page 2-5 of the 19th edition of the ARRL Antenna Book.

Another way to reduce the length of a resonant dipole is to attach large conductive areas to its ends as capacitive hats for loading. This is almost lossless as compared with coils.

The antenna may not be the problem if you are working in the near field. You may have an advantage in the much higher energy very close to the antenna. The antenna`s induction fields are much larger than its radiation field up close. See page 865 of Terman`s 1055 edition.

You might not use a salient antenna at all. You could use a metal 1/2-wavelength slot. See Chapter 9 of Kraus` 1950 edition of "Antennas".

A practical solution may be a 1/4-wavelength, end to end, folded dipole. This consists of a resonant 1/2-wavelength of wire. It takes only 1/2 the space of a !/2-wavelength open-ended dipole. Its gain is only 0.5 dB less than the 1/2-wavelength dipole. Its problem is a feedpoint

resistance of 6000 ohms which may be hard to match. See page 509 of TV and Other Receiving Antennas" by Arnold B. Bailey.

Best regards, Richard H. Harrison, KB5WZI

There's a free demo version of an antenna analysis program,
EZNEC, at http://www.eznec.com It will answer your questions.

A less expensive solution is the SD-20 collapsible fishing pole
from West Bend available through Worldradio. http://www.wr6wr.com
20 feet and a high-Q loading coil does a good job on 40m.

Now, now Cecil. Think positive. Mine is 13 ft taller, much better
looking and does not smell like fish. Besides colapses to less than 4
ft. Will hold up a 40/80/160 half wave dipole or "V". Four of 'em will
support a full wave loop at 160, 320 even!!
With proper guying, no doubt will handle a Tail-Twister and 12 element
log periodic. Get rid of them negative waves radiating from your fishing
pole Cecil. Get a real and positive wave making MFJ high flyer! :o)
And all the children cried "Yea verily, and glory be unto MFJ (and Butch)"!

2872. Re: How do radio waves work?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-23 20:40:18 UTC
From: "aunwin@insightbb.com"
Message-ID: <SS5Td.21403$zH6.5499@attbi_s53>
Source record: 81611

But ofcourse I see it that way but I am not a scientist and I visualise
radio waves and photons my own
way even tho it may be in error. As for color I can see that also as in
infra red pictures but I am not sure whether birds see photon maps in black
and white or in color. .I wonder if that is why whales beach themselves and
even after they are towed away to sea they 'look' at their distorted map and
head right back to the beach!
And with respect to your terminology of 'photon reflection'.. is that not
how the dish works as there is no resonance or
or capacitive/inductive occillations that allow then to reunite with free
electrons, in other words a direct reflection off the dish face so that all
impacts can be focussed to a single point without interference from
electrical fields as in nearby near resonant elements ? Oh if Tom W8TI was
still with us, the director /reflector augument would immediately ignite
again
and various opinions would flow again and learning would increase.

Source record: 81612

Drive a metal pipe in the ground and attach your new MFJ 33 ft.
fiberglass collalpsable non-fishing pole onto it. The MFJ pole has a
1.3/4 in. od size base and probably about 1.5 in. ID. so the MFJ pole
will just slip over the pipe for support. You drive a an 8 ft. pipe
down 4ft. and you have one tough support/ground.

Most electrons in comsumer electronics are moving only a few cm/sec to
m/s. Slower than most people can run.

Dave

2875. Improving ground for a Vertical dipole worth it ?

One of our club members has one and he uses it while camping. He hangs
a wire on it and runs a few radials and operates 20 and 40 meters. He
used it at our last JOTA operation in a local park with good results.

Not so much that any change will fill in the cone.

G. White wrote:
"Output Z is irrelevant."

This is an old argument in this newsgroup. I became convinced long ago that there are cases in which impedance is very important.

"Transmission Lines, Antennas, and Wave Guides" by King, Mimno, and Wing make a clear and concise case for the princuple of conjugates in impedance matching on page 43:

"If a dissipationless network is inserted between a constant-voltage generator of impedance Zg, and a load of impedance ZR such that maximum power is delivered to the load, at every pair of terminals the impedance looking in opposite directions are conjugates of each other.

To secure maximum power output from a generator whose emf and internal impedance are constant the load must have an impedance equal to the conjugate of the generator`s internal impedance."

Radio transmitters don`t produce significant harmonics. It`s the law. They are linear power sources. We can and do tune them for all the power they will produce under their particular operating conditions of drive and d-c power supply. They operate at more than 50% efficiency which means that they don`t take power 100% of the time, but are switched-off during part of the r-f cycle. Output impedance is thus an average over the entire cycle. It`s OK. We have no harmonics. Gaps are filled by the tank circuit and other filters. The radio is a proper source. The impedance added by off-time is called "dissipationless resistance" because no power is lost in the radio while it is switched-off.

Best regards, Richard Harrison, KB5WZI

Hi Butch, Get one, you will like it. I have had one for several
years, it's not really new. I have used it to support verticals in the
back of my pickup, truck body was counterpoise. Operated 80 and 40
with an L network tuner at the base.
The best results was using the 33' pole as the center support for an
inverted vee. You can't get the apex up to 33', because the pole is
too flimsy, but you can get it up 25 to 30'. Vee was a 100' doublet
fed with 450 ohm ladder line and a tuner. All sorts of tricks to
quickly erect, and take down the system. The antenna gives a good
account of itself on 80m-10m.

Sure, you can further reduce losses, but I couldn't really tell
you if it's worth the trouble or not...Up to you I guess...
But note that BC stations using 1/2 waves still use 120 1/2 wave
radials in most cases. Or I believe anyway. It would take a
lot less wire to just elevate the antenna..If you had it up
higher, I doubt you would see much difference, radials or not.
In that case, you are more worried about feedline decoupling,
than ground loss. When I run 1/2 waves, they are always elevated
a good bit. IE: 10m...Usually 20-30-40 ft depending on what
mast I'm using. In a case like that, ground radials would
pretty much be a waste of time and wire. MK

I wonder exactly what happens when you run ladder line say next to a 1''
metal pipe spaced about 1" apprt

is it just that the ohms that change would it be a bit or does it
swing waaaay off??

tnx

Moving the antenna higher will reduce ground losses. Should be easier
than burying radials.

What happens is rather complex. In short, you make a balanced
transmission line, unbalanced. Transmission lines do not radiate,
unless they are unbalanced. Obviously, when you unbalance a
transmission line, everything changes due to common mode radiation of
the line. Exactly how much??

Most birds have color vision - most mammals don't.

> And with respect to your terminology of 'photon reflection'..

If I remember correctly, the theory is that photons are not
reflected but instead are first absorbed and then emitted but
my memory might be wrong.

The problem with metal and ladder-line is at the voltage antinodes.
The peak-to-peak voltage at a voltage antinode is about ten times
the power when the SWR is 20:1 (if memory serves me right). Running
1000 watts with an SWR of 20:1, that's about 10kv between the
conductors at a voltage antinode. If there's no metal, your finger
will do. :-)

2891. FT-857D and ASAT-120 question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-24 03:43:33 UTC
From: "Joe S." <nobody@nowhere.net>
Message-ID: <cvjigr0lkm@news4.newsguy.com>
Source record: 81531

I trust folks on this NG can stand one more question from me. Thanks to those who have replied.

I am considering purchasing an FT-857D and ASAT-120. As I understand it, the rig communicates with the antenna by coupling a control voltage to the coax and the only connection required between the rig and the antenna is the coax. The antenna does not require a separate connection to 12VDC -- right?

When I first key up the rig with the ASAT-120, is there a learning function for the rig and antenna where I tune to each band and let the antenna and rig remember the settings for each band?

Does the antenna automatically tune itself when I change bands, or, is there an UP-DOWN switch on the rig that I must press while watching the reflected power on the rig's meter?

Thanks.

Albert Einstein, when asked to describe radio, replied:
"You see, wire telegraph is a kind of a very, very long cat. You pull his tail in New York and his head is meowing in Los Angeles. Do you understand this? And radio operates exactly the same way: you send signals here, they receive them there. The only difference is that there is no cat."

Thanks, Harrison and Gene,
Actually this product is going to be deployed in about three months time in one of our public sectors. And it really gives me and my boss nightmare every night. For small company like us, there is no choice but to grab everything we could to deliver.
The original prototype is well designed and tested. the frequency is 433 m. Therefore quarter wave length would be about 17.2 cm, which would be too long for a commercial handheld product.
Our task is to re-package it and produce. And that is why i need to modify the antenna. I tested quite a few antennas including loop, semiloop, modified dipole and microstrip antenna as given in http://www.rfm.com/corp/appdata/antenna.pdf
I am using copper fold to make the antenna plane and the groundplane. However, the results is far from satisfactory.
For the above mentioned antennas, i did not changed the matching network given in the transferred design which caters for 17.2 cm antenna. Do i need to do so? Thanks.

Hi J.S.

Cebik says concerning the Inverted L antenna- which is similar to the vertical Dipole that : "There is little evidence, despite the vertical position of one arm of the antenna, that the inverted-L would benefit from a ground plane beneath the antenna. The actual low-angle gain of the inverted-L will, however, vary with the quality of the soil in the region of reflection at a distance from the vertical arm. All patterns were taken over average soil, and soils that are either poor or better than average will tend to show a higher gain and lower take-off angle, at least on the fundamental frequency."

You might do well to read his articles at : http://www.cebik.com/radio.html
He has quite a few dealing with the effects of different radial systems for vertical antennas.

Food for thought and it might save you time and back breaking labor.

Hi ML

Keep the Ladder Line 3X it's width away from the metal for 300 ohm twin lead that would be about 2 " For 450 ohm Ladder line it would be about 5 " a twist in the portion of the line near the metal object about every 18" or so will also help. Remeber though that the portion of the line near the metal object must not be allowed to sway in the the wind if it does it will cause the impedence to very sometimes widly as the line moves closer then further away..

I've found the above to be very accurate and have not had problems in many installations over the years.

As I understand it the ATS-120 is just Yaesu's version of a screwdriver antenna. I believe you still need to feed control current thru a cable and not the coax. Not having used one somebody please correct me if I am wrong. I'm still using my MP-1 yet, too cheap to buy a "screwdriver type" antenna.

Yes. Refraction and reflection can change the direction of a radio wave.

My physics book says:
"The unifying concept (for all electromagnetic radiation) here is that
electromagnetic radiation is produced when electric charge is
accelerated. We have seen this illustrated for radio eaves. As charges
rush back and forth along the antenna, they are undergoing rather rapid
accelerations, especially at the two ends."

Best regards, Richard Harrison, KB5WZI

==========

Without any doubt, Cebik is the finest author on radio antennas. The extent of coverage of practical subject matters, numerical accuracy and use of the English language are beyond reproach.

How he manages to find time even to keep his web-site in good working order is amazing.

But even for the above-average-intellect amateur, the amount of detail is too excessive to take in. Few people have time available for a complete study. And I'm an approaching, still willing to learn, octagonarian.

What is needed is a very much abbreviated summary, just the essentials of his works. Perhaps in small book form. But this can be produced, without unintentional distortion, only by Cebik himself. Does such a work exist?

==========

I have searched without success for the behaviour of simple antennas in the presence of so-called poor ground soils. Can't find much in Cebik except doubtful, expensive computer programs.

The 'constants' of ground soils are Resistivity (Conductivity), Permittivity and Permeabilty. (In the absence of magnetic material such as iron in the soil permeability can be neglected.)

It is generally accepted that ground loss increases as resistivity increases above that of salt sea water. But this cannot be universally true. Taking the extreme case of soils which approach insulators (solid granite rock and arid desert sands) it is obvious soil loss falls again to very low values.

There MUST be values of resistivity at which soil losses are at a maximum but which reduce at higher values of resistivity.

Here we are concerned with buried ground radials. It is submitted that maximum ground loss occurs at lower soil resistance values than are

upposed - if they are supposed or imagined at all!

Suppose soil resistivity is 377 ohm-metres, not a very high value, but it happens to completely absorb, without reflection, radio waves received from an antenna. Is this a suitable candidate for maximum loss in the ground?

The statement, for simplicity, ignores permittivity and the angle at which radiation strikes the ground. But you get the idea.

Has anyone any info on this subject?

Of course, I may be trolling, just to catch old-wives. ;o)

Back in the 1950s we used to install TV antennas on 30 and 40 foot steel masts to get a 100 uvolt signal on channel 2 with a 10 or 12 element yagi. We used regular 300 ohm twim lead and twisted it before putting it into the slot of the standoff. the standoff were about 4" long. The twisting did two things: minimized leadin pickup and equalize any stresses from wind. What happens when you transmit with high SWR is out of my league.

So can gravity. :-) The earth's gravity bends the
radio waves by a very slight amount that can be
calculated if not measured. The earth's gravity also
affects frequency since it affects the length of a
second in "cycles per second". :-)

Go to groups.google.com and look up the thread "Just a comment on losses in the ground", in mid-January 2002, in which we both participated. The posting I made on Jan. 13, in particular, had a fair amount of information on the topic, but other postings in the thread are worth reading.

Cecil, W5DXP wrote:
"So can gravity."

My physics book says:
"--Gravity waves, which should have many similarities to electromagnetic waves even though as far as is known there is no direct connection between the twp types of waves."

Also something the book, although I can`t find it right now, says:
Masses don`t exert gravitational forces on each other based upon where they have been but instead upon upon where they are located right now. In other words, there is no delay in the transmission of gravitational forces. This is different from electromagnetic forces which are transmoitter at no faster than the speed of light.

If the velocity of a gravitational wave is infinite, how could frequency and wavelemngth have any meaning for it?

I'm talking about the effect gravity has on EM waves.
Einstein predicted that the light passing close to
the sun would bend. It did exactly that during a total
eclipse of the sun within the accuracy of the measurements
possible at the time.

EM waves don't travel in a straight line around a Black
Hole which sucks them in from all directions never to
be seen again.

And we know that clocks located at ground level run
slower than clocks located on mountain tops. Gravity
warps time as well as space.

I'd have to look at the articles later...But, as it is, I would
have to disagree with that. An inv-L is nothing like a 1/2 wave
vertical. He may be referring to an extended version, but normally,
an inv -L is a single wire loaded, 1/4 wave vertical,
and relies on the ground connection.
Max current is still at the base, and you can lose a lot to ground,
if it's poor. A longer 3/8, etc L would show lesser losses, but
radials would still help some.

Mark,

In the article quoted, Cebik was describing a half-wave "L" fed at the corner; basically a bent half-wave dipole in an odd orientation.

He fully agrees that the more typical base-fed quarter-wave "L" would benefit from radials.

2912. Velocity factor and impedance of ladder line

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-25 00:14:25 UTC
From: Jim Leder <k8cxm@spam.fuse.net>
Message-ID: <z5uTd.830$Eq2.676@fe37.usenetserver.com>
Source record: 81551

What is LIKELY to be the true impedance and velocity factor of 450 ohm window 18AWG solid polyethylene ladder line? I see everything from .85 to .95 and 375 to 440. Most seem to think it's around .865 and 390 ohms. Is this close enough? I have no way of actually measuring it.
BTW, same as what the Wireman sells.

Sorry for asking a question that's been asked before, but it does have many ambiguous answers and I'm not sure what it really is. I'm using for a matching stub and need to fairly close.

Thanks...

2913. G5RV (Yet Again)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-25 00:27:51 UTC
From: wizard12342002@yahoo.com
Message-ID: <1109291271.142059.158490@g14g2000cwa.googlegroups.com>
Source record: 81552

As someone who is relatively inexperienced with the hobby, I am amazed at the confusion and mysticism surrounding the "G5RV" antenna. It appears to be nothing but a dipole, with a length of "balanced line" to transform the impedance to a better match for coax at certain frequencies.

A little consideration reveals that this antenna should suffer from unwanted return currents unless a balun is used (like any coax-fed dipole), and substantial loss in the coax at certain frequencies. So why is this antenna better than two pieces of reasonably long wire driven with balanced line and a tuner? What am I missing?

(A) The G5RV feedpoint impedances are relatively low within some of the
ham bands. (B)It's a coax-fed antenna which does not need a balanced
antenna tuner which are scarce, complex and expensive.

It is fine to leave it plugged in. If it is UL listed it should be as safe
as the millions of them in service.
Unloaded they should not develop as much heat as a loaded one.

==========

Well done! You are correct about the G5RV in every respect.

As a multi-band HF antenna it is just another dipole without any magical properties.

With the coax (Zo unspecified) its loss is greater than other dipoles.

Its balanced feedline impedance Zo is not specified. This important performance parameter can be anything you like and the antenna will still remain a G5RV.

It has an approximate impedance match at only one frequency, 14.15 MHz. You will be very lucky to find a resonance in any other band.

The impedance match to coax at 14.15 MHz is not at the desirable 50 but 75 ohms.

It has a cloverleaf radiation pattern only in the 20m band, sometimes praised as desirable if you work from South America into both Europe and the USA as G5RV often did.

As with other balanced line fed dipoles a current or choke balun is best when converting impedance from a balanced line to a tuner plus 50-ohm transmitter.

But the biggest joke of all is the half-size G5RV. Mr R L Varney must be turning over in his grave.

Reg, G4FGQ

2922. Re: ladder near metal?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-25 02:10:18 UTC
From: Dan Roth <dpvjroth@locl.net>
Message-ID: <421ec074@news.greennet.net>
Source record: 81561

I was curious as to the characteristic impedance sensitivity to height variations of parallel line over an infinite perfect conducting plane (not the same problem but it may give some insights to the pipe question). The characteristic impedance formula for this appears in many handbooks and transmission line books. Each line is a height h above the conducting plane and the distance between the two lines is W. I chose the wire spacing, wire diameter and dielectric constant to give a nominal impedance of 400 Ohms when h=infinity. Here are some intermediate results:

h=0.5W , Z=363 Ohms
h=W , Z=388 Ohms
h=2W , Z=397 Ohms
h=3W , Z=399 Ohms
h=4W , Z=399.6 Ohms

The 3W rule offered by Dave is apparently very conservative and leaves some margin for cable movement due to wind as he suggests.

Getting back to the iron pipe case, for h values less than W, other issues such as Ohmic loss and ferromagnetic loss may come into play.

I live in a harsh winter environment with lots of ice, wind and snow. I am looking at ways to improve the reliability of my antenna. I don't want to do repairs in the winter!

Is there a chemical that improves the reliability of the electrical connections between telescoping antenna elements? (e.g. telescoping elements used in a vertical)

Rob

Nice articulation. I don't know who OM is, but RF transmitter power amps are
not "impedance matched." Neither are audio power amps for that matter.

It is a pretty good antenna on 80m, 40m, 20m, and 12m because
the 50 ohm SWR is relatively low on those bands. A dipole fed
by balanced line and a tuner may perform better or worse than
a G5RV depending upon the configuration. If one knows what one
is doing, the 100% balanced line approach is best and can be
done without a conventional tuner as explained on my web page.

It has a multi-lobed pattern on all frequencies
above 14 MHz. A 102' dipole has a beautiful clover-
leaf pattern on 17m.

> But the biggest joke of all is the half-size G5RV. Mr R L Varney must be
> turning over in his grave.

Antennas are scalable with frequency, Reg. The
102' G5RV is a pretty good antenna for 80m, 40m,
20m, and 12m. That makes the 51' half-sized G5RV
a pretty good antenna for 40m, 20m, 10m, and 6m.
When Mr. Varney designed the G5RV antenna, there
were no WARC bands.

"OM" is an amateur radio term. It is short for "Old Man". It is a
respectful term for all other males that is quick to transmit via Morse
code. Richard Clark appears to be an amateur radio operator or the like.

RF transmitter power amps are certainly "impedance matched" to the
intended load. Take a look in the ARRL "The radio amateur's handbook".
If you have the 1944 addition, you will need to start reading at page 96
in the lower right column. If you don't have that, try Motorola's AN-721.

As for audio amp, you are 1 for 3 my friend.

If the elements are aluminum, there's a connection compound made for
aluminum
There are several brands and trademarks two of the names are "NoAlox" and
"Penetrox"..
This is for the contacting surfaces in the telescoping sections.

- or move down below the 38th parallel where all antennas last twice as long

I thought this may or may not be a good place to post but not sure
where elese i'd go

The other day I managed to put up my antenna on the roof.Looks beautiful
up there, I thought that was the hard part...

murphys law applied , got in over my head ,

My plan was to drop the coax down a floor mounted vent shaft about
2'x2'. the tv and sat cables are routed this was my plan was to just
copy this method

however it has a 'cap' on it with flashing etc to waterproof it, i
can't remove it , i am not a roofer or a pro installer.

therfore my plan on wiggling the coax into the hole (which i can do)
and then downwards into the shaft failed it was too stiff to turn the
tv guys must have removed the cap

that cap needs to be removed

question

does anyone know of a really good licensced/insured/bonded prefessional
either roofer that can assist me in removing the vent cap and replacing
it OR a cable installer that can handle removing this kind of stuff
and droping the cable down the shaft

i must use a pro' since the building just spent a million on a new roof
and got a waterproff warantee that prohibits them from just doing what
ever i must be profissional

i know this is outside of the favor catagory and i am understanding this
is a for hire job

i am in the Bronx , NY should anyone know of any good such contractors

the vent shaft is straight so i would suspect after that cap is removed
the coax can be droped down the vent and pulled out on my floor vent
along w/all the other coax i mean if the cable tv and sat tv guys
could do it ..

scope of work

remove sheet metal vent cap flashed in and waterprofed, drop cables
down vent to my floor along side of the existing cables , replace vent
cap as it was
pull cable out of vent hole where other tv cable are on my floor
end scope of work

any recomendations for good people/companies is appreciated

thanks email can go to

myles remove this at, dti , dot net

Myles, I'm a long way from the Bronx and it's construction codes, but down here on the Gulf Coast we would just drill an appropriate size hole in the vent cap, install the coax, and then seal up around coax. Should do just fine

Do what you want, but personally I wouldn't mix transmitting coax in a
vent shaft with receiving coax being used by your neighbors to receive
TV and satellite signals. You may interfere with their TVs and
stereos.

Maybe there's another route to bring the coax down to your residence?

Al, KA5GV wrote:
"If not, what would be a good solution other than plugging the unit in and out?"

Overheating is a fire hazard eliminated by a fuse or circuit breaker which limits current to a safe value.

The power circuits in your house may be protected with 15-amp breakers. The wiring is then safely chosen to carry 15 amps with no danger that the wires will overheat.

15 amps in your wall wart may set it on fire with no help from your load-center. This can be prevented with a fuse or breaker on the wall wart by itself which limits the current to less than it takes to set the device on fire.

Best regards, Richard Harrison, KB5WZI

A CMOS Class-E amp is in full saturation (0.5v at 2a)
for 10% of a cycle and off (12v at 0a) for the other
90% of a cycle. The tank circuit changes the digital
energy to analog energy by filtering out everything
except the fundamental frequency component. How
in the world does one determine the steady-state
impedance of the CMOS source? Isn't the best one
can do with a digital switch is to keep it within
specified parameters? The CMOS device dissipates 2
watts for 10% of the time - therefore 0.2 watts
steady-state.

It appears that I may have canceled an earlier posting
by accident so will repeat it.

A certain Class-E CMOS amp is in full saturation for
10% of a cycle, 0.5v at 2a. For the rest of the time
it is off. The supply voltage is 12v. What is the
steady-state impedance of the source at the fundamental
frequency?

Sigma

Although I am confidant that I could design and build an antenna from the above sited antenna concept, I have way too litle knowledge of your restrictions. If you did want to get some help with this antenna maybe you could write a more difinitive description of your needs and restrictions for the really good antenna guys who read this antenna news group.
If your "specs" are realistic, I'd bet money that even I could design a satisfactory "semi-loop", and I might be one of the least prepared antenna designers who frequent this site.

Jerry

My stereo amp has a spec on output impedance. As I recall, it was around
0.16 Ohms. Intended load is 4 - 16 Ohms.

I'm sorry, but they are not. Nor are any power amps that I know of. Efficiency (and thus necessarily output swing) is what matters for power amps. To maximize swing requires load line matching, not impedance matching.

If you want to study RF PA's I suppose Cripps is one of the best I know of for a modern text:

Exactly Cecil. That's exactly why I said the concept of impedance is dubious for large signal devices and thus provides a second argument, albeit weaker, against the "impedance matching" idea for power amps.

"The concept of 'output impedance' breaks down
for large signal devices. For example, what is
the output impedance of a class C or D amp taken
when the transistor is on or off?"

The strongest argument for dropping the impedance matching concept is PA efficiency, and therefore maximum signal swing. Obtaining maximum swing is a load line issue.

For what you say here really to be true the transistors must switch very fast. About 25pS switching speed is needed at about 400KHz. If we take that to be the case however, I think you will see why matching still applies.

Lets take the reactive component first. If there is a reactive component to the loading, the current in the switch will have a higher RMS value without that increase in RMS increasing the radiated power of the system. So the reactive component of the matching is fairly obvious.

Imagine that you have a well designed Class-E circuit loaded with the load the designer optimized it for.

Now imagine that you slightly increase the resistance slightly. When you do so, the current into the load will decrease but the voltage will not increase enough to compensate for this.

Now lets assume that you slightly decrease the resistance. Since we are assuming that this is a well designed case, we can assume that the designer took steps to ensure that the output devices would be protected from excess currents. This could be done by reducing the operating voltage of the output section, for example. In any case, the voltage on the load will decrease by a larger factor than the current will increase.

So it is obvious that the reactive part is matched and the resistive part is matched just as it would be in a non-class-E output section.

This needs a 12V transistor that switches in about 25pS. Would that be
likely on a current chip?

Motorola seems to disagree with you. Perhaps more importantly, I disagree with you. The large signal impedance of a transistor working into a tuned load still applies quite well.

> For example, what is
> the output impedance of a class C or D amp taken
> when the transistor is on or off?"

When dealing with an RF output section you don't deal with just one part of the cycle. You can tell if the real part of the impedance is matched if:

(1) If you increase the resistance of the load does the power decrease?

AND

(2) If you decrease the resistance of the load does the power decrease?

>The strongest argument for dropping the impedance matching concept is PA
>efficiency, and therefore maximum signal swing. Obtaining maximum swing is a
>load line issue.

What do you mean by "maximum signal swing" in this context. I can get a bigger swing by leaving the output completely unloaded and hence causing the actual efficiency to be zero.

The reactive component issue is still there too. Reactive loads cause increased currents in the output stage without delivering any power to the load so they still need to be reduced as much as practical.

Tam

An audio amplifier can have an improved capability of minimizing a
speaker's deviation from its desired displacement if it has a low output
impedance. That is, the speaker's cone tends to swing past its desired
displacement when its terminals are loaded to a high impedance.

Sure are. A 30 year ago 500 level course I took called Non-Linear
Transistor Design said so. The way you handle class C etc. is by
handling each harmonic separately in your analysis of the transistor
plus tank circuit. You match to the harmonic you want. It may be the
fundamental, or the third for a tripler, etc.

Correct - in the case of an audio amplifier damping factor is critical
to accurate reproduction of transients. In an RF amp, it is normally
not required or desired.

Evidently, the guy's never tuned up a 40 meter pi-net output transmitter. ;-)

If that's not impedance matching, I don't know what it is! (Oh, "Load line"
matching? What are the two parameters of the load line? Voltage and Current,
right? What's the slope of the load line? Impedance!)

Cheers!

That works because the transmission line is less than 0.01 wavelength.
So impedance matching becomes moot. If the speaker line were 1/4 wavelength
long, there would be almost no signal transferred at all.

Cheers!
Rich

2963. Matched or Not Matched

Newsgroup: rec.radio.amateur.antenna

Arguments about whether the power ammplifier is matched or not matched to 50 ohms arise due to misunderstandings about the meaning of "matched".

Meaning 1.

The PA has been designed for maximum, linear, undistorted power output when loaded with Ro ohms and the load reistance has actually been adjusted to equal Ro. Ro is usually 50 ohms. (There may be additional criteria to define what constitutes an optimum match.)

Meaning 2.

The load impedance Z = R+jX has been adjusted to equal the conjugate of the internal impedance resistance of the PA. (The internal impedance of the PA is usually unknown but the circuit is assumed to behave as if a conjugate match exists.)

The two meanings are entirely different from each other. If there is danger of confusion then the meaning should be stated. Some people already use the descriptions "Zo match" and "Conjugate match".

(Unless you use the specially tapered euphonic cable!)

Actually, if you used a thick enough wire, you could go 1/4 wavelength at
audio frequencies. If you connect a speaker straight onto the mains,
chances are you are going further than that from the generator.

Meaning 3:
The PA has been designed to deliver the maximum power at that load
impedance and the distortion is not an issue.

>The two meanings are entirely different from each other. If there is danger
>of confusion then the meaning should be stated. Some people already use the
>descriptions "Zo match" and "Conjugate match".

Actually meanings 2 and 3 are effectively equal in the case of the tuned
system, if you define the Zo based on the change in output power vs
connected impedance for small changes. Since a lot of such systems aren't
linear, this is the way you end up having to define the impedance. You
can't use open circuit voltage and short circuit current.

Remember that this all started with the OP having a "transmitter". This
would include any needed filtering. He was just connecting a 1/4 and 1/2
wave lengths of bent up wire. His output filter, I assume is just a bunch
of LC sections.

As King, Mimno, and Wing said, a conjugate match is required to get maximum power out of the radio.

Terman says the same on page 76 of his 1955 edition of "Electronic and Radio Engineering."

There is also an Eimac application note on matching their tubes to a load on the final amplifier.

If Larry, Moe, and Curly published an application note, we`d have a crowd of skeptics here. See Terman`s Fig. 3-21 on page 77 of his 1955 edition.

There is nothing wrong with driving a transmission line/antenna from a zero
impedance source. It does NOT change the SWR. The point is that an audio
amplifier with a damping factor of 50 is NOT conjugate matched.

Somebody mentioned Motorola Application note 721. This is what it says:

****
" ..the load, in first approximation, is not related to the device, except
for VCE(sat). The load value is primarily dictated by the required output

power and the peak voltage; it is not matched to the output impedance of the device. "

****

When device people talk about "matching", they mean matching the load to what the transistor wants to see, which is not the conjugate of the output impedance. The way this is done is to build an amplifier, and vary the load until maximum output power is reached. The transistor is then removed, and the impedance looking into the coupling network is measured. The conjugate of this is sometimes listed as "output impedance" on data sheets. Newer data sheets will have an asterisk * next to that, and a note explaining what it means. If you look at Philips literature, you will see exactly the same explanation.

This whole thing has been hashed out here about 5 times during the past year.

If a conjugate match matters two hoots, or is involved in the slightest way with the design of power amplifiers or any other sort of amplifier, why don't tube manufacturers state the internal resistance or impedance in tube date sheets?

It say " Strictly speaking..." is that the section you are refering to?

Yes they do say that but then if you follow the design through, I think you will find that they try to cancel the reactive component. If you then put in the output device protection they didn't include, you end up with the matching as I explained elsewhere. As the impedance moves away from what the designer intended, the radiated power decreases.

The point is that the OP was taking about hooking a "transmitter" to a length of wire. I was talking about the matching from a complete transmitter which I assume contains such protection to this length of wire.

So I guess you just connect your tubes or transistor finals directly to
the coax?

I mean, since it doesn't matter...

Actually, in this case, I was speaking of matching the transmitter's
output to the load. The transmitter already contains gawd knows what L
and C components etc. The OP has a completed transmitter and a hunk of
wire. If he matches the wire to what the transmitter wants to see, the
transmitter will be happy. If he causes a reactive current to flow that
the designer did not design for he will cause added heating in the output
device. If the designer did a good job, the transmitter will protect its
output devices and thus end up producing less power.

Also if he makes the real component of the impedance vary from what the
designer intended, the output power will decrease. Which direction gets
limited by the Vcc and which by the protection circuit depends on the
collection of Ls and Cs inside the transmitter.

Let's assume the designer is an amateur who didn't provide
any protection for his tube's output. The lower the resistive
load, the more current the output device draws until it fails.
What is the output impedance of the device?

And there's the catch. If the load line is the source
impedance, the load (not the designer) effects the source
impedance.

When I first became a ham, transmitters didn't have
any protection at all. They would keep putting out
more and more power until the final or power supply
got too hot.

My 6L6 went out during a contest in the 50's. All I
had to replace it with was a metal 6V6. What's the
source impedance of a 6V6 plugged into a 6L6 socket?

The phrase "output impedance" in connection with amplifiers is ambiguous and likely to result in arguments.

The correct description is "internal impedance" or "internal resistance" and should always be used.

2979. PileupBuster.com - Domain Name is For Sale

Newsgroup: rec.radio.amateur.antenna
Date: 2005-02-26 05:21:45 UTC
From: erfurth@gmail.com
Message-ID: <36ba001b.0502252121.13e8203e@posting.google.com>
Source record: 81518

-NOTICE-

The "PileupBuster.com" domain name is For Sale.

For less then the price of an HF rig you can own the ultimate Ham Radio domain name.

The PileupBuster.com domain has immediate name recognition to everyone associated with Ham Radio. Plus, the sales and marketing potential of this name is unlimited.

The minimum offer on this domain is $1,250.00 (US Dollars). The PileupBuster.com domain name will be sold to the person, company or group that makes the highest offer. International offers are welcome.

This is a Private Auction. No one will see what you offer and you will not be able to see what others are offering.

You may begin submitting your offers on Saturday February 26. No offers will be accepted after 12:00 midnight (Pacific Time) on Friday March 4, 2005.

TO MAKE AN OFFER, GO TO: http://PileupBuster.com When the web page comes up, look right under the PileupBuster.com name. You will see "This domain is For Sale" then click on: "More detailsï¿½" You will then see a box to enter your offer. Enter your offer and then click "Make Offer"

This sale is supervised and regulated by SEDO (sedo.com), a highly respected International domain sales company.

If you have any questions, please feel free to contact me at: erfurth@gmail.com

Good luck.

73s,

Bill

I suppose the same could be said of any block that is
susceptible to having some feedback put around it.
Therefore the term "output impedance" should never
be used at all. And of course, any term that could, or
has ever been known to lead to an argument, with any
uninformed person that might come along, should be
eliminated from our vocabulary.

Uuugh. Mmmmph. Me drag woman to cave by hair.

> The correct description is "internal impedance" or "internal resistance" and
> should always be used.

Nonsense.

If I wanted to speak of an impedance inside of some
circuit, I might loosely speak of it as "internal", but in
any useful discussion, it would be spoken of as either
an output impedance or an input impedance, and, with
most people I have such discussions with, there would
be no need to add that some unknown additional feed-
back not part of the present discussion could alter the
observable impedance.

I hope your post was a troll.

(in <421FBB39.6BB0153C@deadend.com>) about '1/4 vs 1/2 wavelength
antenna', on Fri, 25 Feb 2005:

>I'm sorry, but they are not. Nor are any power amps that I know of.
>Efficiency (and thus necessarily output swing) is what matters for power
>amps. To maximize swing requires load line matching, not impedance
>matching.

What is a 'load line'? A straight line on an I/V graph? What does the
gradient of that line represent?

The problem is that people say 'output impedance' when they mean 'load
impedance'. To prevent misunderstanding I use the term 'output source
impedance'.

There are also some people who use 'input impedance' when they mean
'source impedance'. I don't talk to them. (;-)

Apparently, I'm not following the same conversation here, because I
thought that the impedance matching network (in the instant example, the
pi-net output of the transmitter) was what translated the load impedance
to the source impedance, matching both in the process.

Thanks,
Rich

I am not certain that a Rhombic for 160 would fit in your 10 acres. In part
it depends on the
configuration of the lot. 10 acres in a square configuration would lead a
side of about 650 feet. A wavelength is 160 x 3.1 or 496 feet. So the side
of the lot is less than 1.5 wavelengths on 160 -- not very long for a
rhombic. Do you have really tall supports for the Rhombic? You clearly have
enough space for a rhombic on 20 meters and perhaps 40 meters.

Do you really want to have most of your power going in only two directions?
This would assume that you could selectively feed one end or the other of
the antenna while terminating the other.

Perhaps one or more 160 meter center fed wire antennas arranged so that you
could choose the one
with lobes in the correct direction for your contact on the your choice of
bands would work out better.

Regards,
Ed, N5EI

G5RV originally designed the antenna for gain on the 20 meter band.
Over the years, various mfg. have made minor changes, but the design
essentially remains unchanged.
(The "double-size" for 160 is not an efficient antenna. Better to feed
260' of wire via ladder or open wire line.)

All currents are fed via the coax and there is no separate 12v line. The rig knows where the ATAS is tuned to and adjusts it accordingly when you press the tune button. The ATAS can be manually tuned using the up and down buttons but in my experience this is never required. Even on 40m (7.0 - 7.2MHz here in the UK) once tuned to the centre of the band retuning within the band is not required.

I have changed the standard whip on my ATAS 120 for one that is about a foot longer and it works great on all bands including 30, 17, 12 and 11m. I have never used it on the VHF or UHF bands as I have a separate antenna for these bands. Drop me an email if you want any more information.

I live in a similar location to you and have found the 450 Ohm ladder line to be pretty useless in the wind. It seems to break every couple of months and I have to keep repairing it. I made some open wire feeder using standard speaker cable spaced about three inches with the spreaders every meter and it lasted for several years. For the spreaders I used short sections of square PVC trunking, drilled a hole at each end just large enough to thread the wire through then used Superglue to lock them in place. It works just as well than the commercial stuff but with less loss.

Maybe I inferred wrong. From your "load line equals
impedance" statement above, I inferred that you were
implying that the load line *is* the source impedance.

That's true for the solid copper wire stuff. But
I have used the #14 stranded stuff ever since it
was introduced and it has never broken. AZ and
TX have their share of wind.

What about a full -wave loop? Approximately 150 feet per side for a
square. Feed it from a corner or the center of one side. Tune it for
all bands.

Its just one of many options.

Al

Do you unplug your TV? It is always on, drawing some current . Then
there is the electric clock. The list could go on and on in most
households.

That is -- If your mind is already made up, why ask a question about
wallwarts on an antenna news group

No, just trying to make the point that it does, in fact, _have_ an
impedance. (even if it's running class E.) What that exact impedance is,
of course, is left as an exercise for the reader. :-)

And another thing - in a transmitter, the impedance matching only happens
at the one frequency, which is a lot different scenario from, say, a
stereo. This could be a confusion factor here.

Thanks,
Rich

Nice antenna, designed after the UKSMG design I
"borrowed" (tee hee) from GW0WFH.

http://www.uksmg.org/longwire.htm

This is a great working antenna, with 12dB
measured gain over a dipole. It isnt a beam, but
it sure is better than a dipole!

$140.00 plus $6.50 shipping in lower 48 states.

Email N8WWM@arrl.net for more information and
photos. I'll take paypal, a check, money order,
whatever.

John Woodgate wrote:
"The problem is that people say "output impedance" when they mean "load impedance".

Quite right. I`ll use "source" and "load".

Current through a load depends on the voltage. Ratio of volts to amps is the impedance. A source with the same resistance and offsetting reactance to the load enjoys a Goldilocks relationship with its load. The source`s volts and amps perfectly match the demands of the load. It`s just right. There`s no surplus of either volts or amps when source and load are connected. Its a match. Only a matched source and load deliver all the power available in a source.

If we have too much resistance in our load, it doesn`t take as much power as it could.

If we have too little resistance in our load, too much power is lost in our source.

The perfect match of equal source and load resistances, with the reactance neutralized, is the only condition permitting maximum power transfer.

Somme amateurs want all the power they can get from their transmitters.

Best regards, Richard Harrison, KB5WZI

Kathy

Thats a really interesting antenna. And it isnt too expensive either.
Could 8 of them be connected in parallel to get 21 db gain over a dipole?

What's the S22 of an IC-756PRO? With that figure,
S22^2 is defined as:

Power reflected from the network output divided by
Power incident on the network output.

Better yet, we can then calculate the reflected power
dissipated by the IC-756PRO.

Therefore, the key to converting the non-linear source to
an equivalent linear source lies in a Fourier analysis?
Do the other-than-fundamental terms in the Fourier analysis
encounter a low impedance or a high impedance?

>Do the other-than-fundamental terms in the Fourier analysis
>encounter a low impedance or a high impedance?

Yes. Not facetious; the impedance matching network can be configured to
minimise individual or a few harmonic emissions by adjusting its
impedances at harmonic frequencies. Either high or low (or perhaps both)
can minimise the emission, depending on the configuration.
--
Regards, John Woodgate, OOO - Own Opinions Only.
The good news is that nothing is compulsory.
The bad news is that everything is prohibited.

==========

Cecil, I havn't the foggiest idea what an IC-756PRO is except that it is something which comes from that excellent manufacturer Icom.

But your extremely brief question is the most hillarious ever asked on this newsgroup. You are still at the best of your form. I can't stop laughing.

The best I could do is ask what is the S22 of a 6J5. One thing for certain, it is not mentioned in manufacturer's data sheets. Yet ARRL simple PA design rules manage very well without it.

Yours, Reg.

I've been looking over the options and now have decided to have the ladder line drop pretty much straight down to an LDG RT-11 remote tuner. Ladder line will be 22 feet long which will put the RT-11 and the 1:1 balun up out of harm's way on a treetrunk facing the woods. I'm going to direct bury coax and use some 18-10 direct burial irrigation wire for the controls.

This will keep the ladder line out of the shack and also make it more stealthy neighbor-wise.

Hope to have it all on the air with an /AG call by mid-April!

tnx
jtm

At the point where it fails, the output goes to zero, I assume. If so,
wouldn't that be the impedance as I've been defining it.

Yes for the purposes of the OP's case it is. He is trying to use an
existing transmitter design and a hunk of wire. This seems to be the part
of my argument that people are missing. I suggested he use a matching
network to match the wire to the transmitter's output.

Free radio,
No, a rhombic wouldn't be a good choice for an 'all band' antenna. I think a better choice would be several antennas optimized for particular bands, as high as you can get them. But, since you rule out towers, and I've no idea what trees you may have on the property, the multi-antenna thingy may not be a good choice either.
Lots of help, huh?
'Doc

PS - The large horizontal loop idea isn't a bad one...

Funny: try as hard as I can,with EZNEC, can come up with
4.12 dBD gain, and a f/b ratio of 1.44 dB (in free
space), and at 20 ft elevation, has about .1 dB gain
over the free space amount from ground reflections!
Does this mean that EZNEC has a BUG ??
I don't think so! And, at the price-
could double the amount and get a antenna with REAL gain!
As for me , I'll stick with my 7 El M2, with "only" 10.5
dBd gain ! I'd like to see the field, and equipment that
was used to measure that 12 dBd gain-- I don't think so!

Whether the harmonic impedance is high or low would affect
the efficiency, no?

Is an amp that fails at one minute with 100w FM
better matched than an amp that fails at two minutes
with 100w CW?

RG> And another thing - in a transmitter, the impedance matching only
RG> happens at the one frequency, which is a lot different scenario from,
RG> say, a stereo. This could be a confusion factor here.

RG> Thanks,
RG> Rich

There are a couple of things meant by matching. The usual notion has
to do with the plate resistance of tubes. When used in a linear mode a
tube has a given plate resistance. To get the most power output from a
tube its plate resistance must equal the load. The available plate

current curve and equivalent load then must match the supply voltage. A transformer is needed to adjust the typically low value load resistance to the much greater plate resistance.

The other notion of matching has to do with using a switched voltage to synthesize the right output voltage and current to drive a given load. This type of transformation is done by using sampling over time.

Another type of transformation uses a resonnant tank circuit which, like the above transformer, can adjust the load resistance to equal that of the source resistance by a choice of the proper tank network reactances. This is a single frequency only matching however.

Transistor audio impedance is never matched since an extremely low source resistance is desirable for speaker damping. Musical instrument tube amplifiers are somewhat between these since the tube power must be transformed to match the high voltage supply low plate current to the high current low voltage load, but yet must present a low source resistance damping to a speaker so uses negative feedback for this.

A*s*i*m*o*v

... Ok, I pulled the pin. Now what?.....Hey! Where are you all going?

I think the question can only be answered by 'It depends..'. For
example, it is 'affected' if it's changed by 1%, but is that
significant?

I read in sci.electronics.design that Reg Edwards
<g4fgq.regp@ZZZbtinternet.com> wrote (in <cvqsannhk1@titan.btinternet.
com>) about 'Say what you mean.', on Sat, 26 Feb 2005:

>The best I could do is ask what is the S22 of a 6J5. One thing for
>certain, it is not mentioned in manufacturer's data sheets. Yet ARRL
>simple PA design
>rules manage very well without it.

You wouldn't expect to use scattering parameters for a 6J5. But change
that to 7194 and the question is not so facetious. (;-)

I had a look at the referenced website which claimed up to 4db gain in several directions but NEVER 12 db gain over a dipole. Now here I realise it comes down to semantics. 12db gain over the ENDS of a dipole. Yes. 12db gain over a dipole lying on the back lawn. Perhaps. 12db gain over a similarly installed height, rotatable dipole. No way in Hades.

It's a lot for a 40m end fed dipole which, by the way, is what I am using on 6m at present.

Joe;

Only the connecting coax is required to tune the ATAS antenna.
You simply push the tune button on the 857 after changing bands and the
antenna tunes to the frequency of the 857. I briefly used an ATAS-100
with an FT-100D and presume its tune functions are carried over to the
replacement 857.
Good luck,
Jim, K4SQR

Jerry, I posted to this group because it is one of the most knowledgeable and dependable.

The TV, clock, etc. are not unloaded like the transformer I asked about. I don't know if it is safe to leave an unloaded transformer plugged in, so I asked. I placed a resistive load across the transformer to keep a slight load across it, but not being sure if this is OK or not, I decided to unplug the transformer for safety.

Message-ID: <4221e38d_2@newsfeed.slurp.net>
Source record: 81380

Many posts under the drifted thread "1/4 vs 1/2 wavelength antenna" give various views on the physics of generating the maximum safe load power from an RF amplifier. To those posters I present this reality.

Modern, solid-state FM broadcast transmitters WITHOUT TUNING OR OTHER ADJUSTMENT will produce their full rated output power into a 50 ohm load at any frequency in the 88-108MHz FM broadcast band, and with ~uniform, and high PA efficiency (80% or better, typically). These transmitters have no resonant circuits in their entire RF chain except for their output lowpass/harmonic filter. It is possible to slew the tx freq from one end of the band to the other in the time it takes for the exciter to lock up on the new frequency (a second or two).

This reality seems at odds with many of the declarations made in this NG, and perhaps may inspire some posters to further research their opinions and theories.

Look at it this way, there are millions of unloaded door bell transformers
in the US.
The only time they are activated (loaded) is for about 2 seconds when
someone rings the bell. Mine usually rings once a week for pizza and a
couple of times for visitors.

The transformers will draw a slight ammount of current so you may save a
dollar or two each year if you unplug it.

I recently purchased an old crank-up motor driven 60 foot tower that I would hope someone could help ID for me. The motor belt drives a gearbox, which turns the cable pulley. It has a approximately 1 foot by 18 inch control box which has two high current relays and two glass contained relays. The glass-contained relays are in old 8 pin tube sockets. The tower is in three 20 foot sections.

The tower, itself, is in good shape. I would like to re-build the control circuits and put the tower in service. Any information anyone can give me on this tower will be greatly appreciated. A circuit diagram of that control box at the base of the tower would go a long way. See at www.winlyn.us/tower.jpg.

Hi Richard,
You may have meant this to go to a different group,
But I must point out the resonant circuits in the output of the exciter.
Usually the exciter has an output lowpass/harmonic filter.
But you knew this anyway;)

Read the book _Radio Frequency Transistors Principles and
Practical Applications_, by Norm Dye and Helge Granberg. At
some point in the book, they go to great lengths dealing
with "matching" the input and output of transistors and how
to effect broadband matching schemes. They even mention some
transistors that are manufactured in such a way as to be
internally matched over a particular range of frequencies.
It doesn't hurt to read books by guys who know what they're
talking about.
73,
Tom Donaly, KA6RUH

No, this is the group with the "1/4 vs 1/2 wavelength antenna" thread I referenced, and all the statements under it about matching RF amps and loads across different bandwidths.

> But I must point out the resonant circuits in the output of the exciter.
> Usually the exciter has an output lowpass/harmonic filter.

The practice in top-of-the-line FM systems these days is to use a harmonic filter on the exciter output only if/when it is used as a low-power transmitter directly on the air. Otherwise that filter is redundant, and can reduce the performance of the exciter by a small amount.

I wondered about that. According to the text, I believe the feedpoint
insulator is actually an insulating sleeve to get the antenna inside
the author's attic.

Basically it appears to be nothing but a 65 foot long wire for 6
meters. If I attached a 65 foot wire to the random wire terminal of my
antenna tuner, I'm guessing I'd have the same thing.

And I'd save $140 :-)

No, you've got the concept backwards. Obviously the worst matched is the
1 o=minute case, next would be the 2 minute case and so on up to one which
runs for about its MTBF at the connected load. This last case would
likely be the one the designer was targeting.

There is very little that is sent in the form of radio waves that is worth
the electrical power to send it. The really sad thing is that much of
what is send via FM is really "voice grade" material. When FM was new,
the material for FM was specially produced to take advantage of the wide
bandwidth and large dynamic range.

It's been thirty years since I "hammed". I was only interested in the
electronics, not the talking, so I dropped out after I got a homemade
solid-state 2-meter rig running.

But I vaguely recall a 5/8 wavelength antenna that had a good
low-angle pattern.

Unfortunately, the OP (is he still here?) was stuck with a box to short to
even fit a 1/4 wave whip. I also think that this box could not be assumed
to be resting on the ground

If you squint at the ASCII art below, you will see more or less the
radiation pattern of a 5/8 whip over a large ground plain.

```
..............................
..............!...............
.........******!*****.........
.........*......!......*........
.........*......!......*........
.........****..!..****...A.....
.......*******..!..*******......
....***.........!.........***...
..*.............!.............*B
********************************
```

If you don't have a large enough ground plain, the notch in the side
labeled "A" starts to go away and the peak at "B" reduces.

This may not be the best pace to post this, but I figured it would be a good place to start. I live in Maine and am trying to get a Massachusetts AM station can anyone recommend a good AM radio or better alternatives to the regular AM antenna that comes with my AM radio from Radioshack? If there are other newsgroups to check please let me know.

It appears that my cold water pipe is made completely of copper (no PVC). If I attach to it right where it enters the house (but on the inside), will this be an effective lightning ground? The electrical panel connects at this point also.

Thanks,

-JJ

As far as the antenna, I'd build a small loop. Small, meaning
less than a full wave, which would be huge for MW...
The good part, is you don't even need a direct connection to
the radio to use them, although you can if you want, usually
using a 2nd coupling loop. So it can be used with *any* radio.
Most smaller radios, it will be like adding a dose of steroids..
And the nulls are very sharp, so you can null out noise, or
other stations. You can build one cheap. The variable cap will
cost the most if you buy it, and you can find them in many old
junk radios, and also old stereo receivers. The ones in receivers
are usually pretty good, cuz they have multi gangs, and if you
tie them all together, you can get a pretty large value.
You can also use switches. If you wanted to tune a freq on
the upper range of the loops design, it's handy to be able
to use just a single small gang, and have a low value...
There are a gazillion designs on the web. I have one at
http://web.wt.net/~nm5k/loop5.jpg
using PVC parts you can get at any hardware, or home depot,
etc.. BTW, the loops work pretty well any time of day, but
where they really shine is in the daytime, and you are receiving
ground wave signals. I can listen all over the state, and it's
almost like being local..My main loop is a diamond, 44 inches
per side, using 5 turns of wire. I have it on a floor stand,
and it rotates. I just lean over and grab it , if I want to
change direction. MK

Hummm..Actually just thinking about it, I think they
usually classify a "small loop" as 1/10 wave or less...
But I'd have to refresh myself...MK

The simple answer is "Yes".

The simple reason is because having a station ground (or any antenna ground) tied to the same point of the building's electrical ground is mandatory, not just an option.

As far as the attachment point being "inside the house", that's not the best arrangement for some situations. It's really phenomenal luck for your station-ground to be close enough to make the home's service entrance ground your station's "single point ground". But not so good to route grounding (down conductor) from a rooftop antenna [inside the house] to reach the same point.

For your electrical service to be grounded at the cold water pipe, this implies an inspector approved the connection, and there must be no break in the bond (all metal continuous) for at least 10' underground. That's an excellent ground btw, better than any driven (10') ground rod could provide. If your station equipment is located very close to the service-entrance ground, you are so lucky! If it's not, like most of us, additional planning is required to have a safe grounding system.

Remember that anything you connect to ground from a rooftop antenna could feel hundreds of thousands of volts potential from a strike. That connection should normally be made straight to an earth-driven grounding electrode outside the home. You would then bond that grounding electrode to the service-entrance ground and your station ground, were they separated.

You can review this in greater detail at:
http://members.cox.net/pc-usa/station/ground0.htm

Hi Jerry, Let me first say that I have never used a 1798, but can
offer some comments for what they are worth.
I have seen the 1798 at hamfests. It is large, and although 20'
tall, it will require guying, and a sturdy bottom support. It will
require a lot of assembly and tuning time. It costs $300.
As for performance, a low dipole, or inverted vee (30'-35') will
probably exceed the 1798 on 80m and 40m. 20m-10m toss-up. 6m and 2m??
As a less expensive alternative, a 100' dipole or inverted vee fed
with 450 ohm ladder line and an antenna tuner will provide equal or
better results 80m-10m. 6m and 2m require additional attention. Since
you will need to guy the 1798, the space required will be larger than
you think.

Personally I don't care if she's a prostitute, I wouldn't talk like that to her! As for what she's done before, it's not apparent in this posting, and even if it was we should attempt to hold our selves to a higher level... Would you have said that on the air? Probably not and why, because people would have attached it to you and thought you a small ignorant person... Whether or not you like her or hate her she's still a woman who deserves at least a business like approach... Jesus! do you talk to you ex-girlfriends like that... You probably don't much like them either...

I don't much care for any woman who can't keep her mouth shut. That's what
is wrong with this country now, women need to be home and know their place.

You sound like one of the spineless weasels who are trained to be
"sensitive" and "attentive" to a woman's needs.

You and you ilk will be the downfall of the once great country.

June Cleaver, where are you when we need you?
